Wolves are unusually numerous throughout the whole of n.w. America, and they are equally at home on the prairie or in the forests, on the mountains or on the treeless plateaus. The bison or American buffalo is now confined to a few regions extending from British America to New Mexico, but it is nowhere as abundant as formerly. The buffalo is hunted by two methods—stalking it, and running it down on horseback; and it is estimated that a quarter of a million bison are destroyed annually. Foxes are very numerous throughout the west, and fox-hunting as carried on in Europe was a favorite amusement with the southern planters before the rebellion. Fox-hunting clubs and packs of hounds have been lately established in New York and a few other places. The American antelope is found all over the open plains of the west. If the pleasures of antelope hunting were more generally known, it would become what hare-coursing is in the British kingdom, and with this greater advantage that it affords much keener amusement, and gives hounds, horses, and hunters a better opportunity of testing their speed, power, mettle, and endurance. Hares are so abundant that they are considered nuisances in many sections of the country, and a good marksman can kill from twenty to fifty a day. In California the hare is hunted regularly with greyhounds. It is the only part of the United States where a coursing club exists. This club is governed by the same rules as those of Great Britain, and its meets are accurately reported. The progeny of the victorious dogs command a high price. The hares are hunted in various ways. One method is to run them down out of cover with slow-hounds, and shoot them as they flee past a stand; another is to course them with greyhounds; and a third way is to trap or snare them. Among the smaller game which often afford pleasant sport are the raccoon, opossum, and squirrel families. The first two are hunted principally at night as they are nocturnal in habits, and are generally killed in the leafy retreats of trees and shrubbery where they take refuge. To hunt wood-squirrels successfully small curs or terriers should be used. See FOX-HUNTING, *ante*.

HUNTINGDON, a co. in s. central Pennsylvania, on the Juniata river, intersected by the Pennsylvania railroad; 800 sq.m.; pop. '70, 31,251. The surface is mountainous and to a large extent covered with forest. The valleys are fertile, producing wheat, corn, etc. Co. seat, Huntingdon.

HUNTINGDON, the extreme s.w. co. of Quebec, Canada, on the Chateauguay river, the New York border, and the St. Lawrence, traversed by a branch of the Grand Trunk railroad; 400 sq.m.; pop. '71, 16,304. It has an undulating surface, and the soil is fertile. Chief town, Huntingdon.

HUNTINGDON, a market t. and parliamentary and municipal borough of England, capital of the co. of the same name, on the left bank of the Ouse. Huntingdon is united with its suburb Godmanchester by a bridge over the Ouse. The Great Eastern railway and the Great Northern have each a station here. There are 3 established churches, 4 dissenting chapels, and numerous schools, one of which is the grammar-school, with an endowment of £100 a year, and two exhibitions for Cambridge university. Large brick-works, two breweries, and an iron-foundry, are sources of employ-

ment. The house of Oliver Cromwell is of historical interest. Pop. of parliamentary borough ('71), 6,606; of municipal borough, 4,243.

HUNTINGDON, SELINA, Countess of, was the second of three daughters and co-heiresses of Washington Shirley, second earl Ferrars, and was b. Aug. 24, 1707. She married, in 1728, Theophilus, 9th earl of Huntingdon, and became a widow in Oct., 1746. Adopting the principles of the Calvinistic Methodists, the founder of which sect was the famous George Whitefield, she made that eminent preacher one of her chaplains, and assumed a leadership among his followers, who came to be known as "The countess of Huntingdon's connection." On Whitefield's death in 1770 she was appointed by his will sole proprietrix of all his possessions in the province of Georgia, on which she immediately set about organizing a mission to North America. Her labors at home increased with her years. For the education of ministers she established and maintained a college at Trevecca, in Wales; removed, in 1792, to Cheshunt, Herts; and built, or became possessed of, numerous chapels in different parts of the country, the principal one being at Bath. She likewise expended large sums in the support of young men trained to itinerant preaching, as well as in private charity. But with all her excellences, she was not indisposed to play the part of a female pope, and had quite a passion for carrying her point. She died June 17, 1791. By her will, dated Jan. 11, 1790, she created a trust, bequeathing her chapels to four persons, of whom lady Anne Erskine, a daughter of the earl of Buchan, was one, for their care and management after her death, when the number amounted to 64. Most of them have become, in doctrine and practice, almost identical with the Congregational or Independent body. There are now about 40 chapels belonging to this connection in England and Wales.

HUNTINGDONSHIRE, a small inland co. of England, is bounded on the e. by Cambridgeshire, on the s. by Bedfordshire, and on the w. and n. by the co. of Northampton. Area, 229,515 acres, almost the whole of which is in arable or pasture lands. Pop. '71, 63,708. It is watered chiefly by the Ouse, which flows n.e. through the s. part of the co.; and by the Nene, which skirts its northern boundary. In the southern districts the surface is diversified by low hills; the northern portion of Huntingdonshire, however, is included in the great fen-country. The soil is various; clay, however, predominates generally. Grain, with beans, rape, and clover, are the chief crops. The county returns two members to the imperial parliament.

The county of Huntingdonshire was traversed by two Roman roads, and Roman remains, as coins, pottery, etc., have been found.

HUNTING HORN, or BUGLE HORN, is a frequent bearing in heraldry. When adorned with rings, it is said to be *garnished*. If the mouth and strings of the instrument are of a different tincture from the horn, this must be named in blazon.

HUNTINGTON, a co. in n.e. Indiana, crossed by the Toledo, Wabash, and Western railroad; 400 sq.m.; pop. '70, 19,036. Surface level and soil fertile. Productions: grain, wool, cattle, and lumber. Co. seat, Huntington.

HUNTINGTON, a city in Huntington co., Ind., on the Wabash and Erie canal and the Toledo, Wabash and Western railroad; 24 m. s.w. of Fort Wayne; pop. 2,925. The city has a dozen manufactories of wooden ware, two iron foundries, two newspapers, library, reading room, museum, etc. Lime-burning is a leading occupation.

HUNTINGTON, a village in Suffolk co., N. Y., reached by the Long Island railroad; pop. '80 (of township), 8,098. The manufacture of bricks is an important industry. The region is to a considerable extent peopled with wealthy residents of New York city.

HUNTINGTON, a t. of Cabell co., W. Va., on the Ohio river, 160 m. above Cincinnati, and 52 m. w. of Charleston; pop. '70, 2,650. It is just below the mouth of the Guyandotte river, and is the western terminus of the Chesapeake and Ohio railroad, and the eastern terminus of a line of steamers run in connection with the trains. It was organized as a city in 1871, and is a place of important manufactures. It is the seat of Marshall college, a state normal school, a bank, 2 newspaper offices, 9 churches, 3 hotels, a foundry, a planing mill, and the machine shops of the railroad.

HUNTINGTON, DANIEL, b. N. Y., 1816; educated at Hamilton college. Through an acquaintance with Elliot, the portrait painter, he was led towards art, and in 1835 began to study under professor Morse, and still later with Inman. In 1839 he visited Italy; returned the next year and began work, but was compelled to desist in consequence of failing eyesight. He was again in Europe in 1854, where he painted some noteworthy pictures. After his return he was engaged chiefly on portraits, but painted also a few historical pictures, among which are: "Henry VIII. and Catherine Parr," and "Mary Signing the Death Warrant of Lady Jane Grey." Thereafter he became a permanent resident of New York, and in the course of a few years painted the portraits of many notable people of the city and country. To the people at large he is best known by the engraving of his picture of "The Republican Court in the Time of Washington," in which there are more than 60 figures, of which nearly all are accurate portraits taken from original paintings. He was for many years president of the national Academy of Design.

HUNTINGTON, FREDERICK DAN, D.D., b. Mass., 1819; graduated at Amherst, and studied theology in Cambridge divinity school. In 1842 he was a Unitarian pastor in Boston, and in 1855 preacher to Harvard university. In 1860 he became an Episcopal minister, and in 1869 was chosen bishop of central New York. Some of his publications are *Human Society as Illustrating the Power, Wisdom, and Goodness of God; Lessons on the Parables of Our Savior, and Steps to a Living Faith.*

HUNTINGTON, JEDEDIAH VINCENT, 1815–62; b. New York, a brother of Daniel. After practicing medicine for several years he became a minister of the Protestant Episcopal church. In 1849 he went to Europe and then joined the Roman Catholic communion. In Baltimore he edited the *Metropolitan Magazine*, and in St. Louis, *The Leader*. He published some novels illustrating conversion to the Roman Catholic faith, among which are *Lady Alice, or the New Una; Alban; The Forest; Blonde and Brunette; and Rosemary.*

HUNTINGTON, SAMUEL, 1732–96; b. Conn.; a signer of the declaration of independence; educated to the law, and was associate justice of the superior court of Connecticut. He succeeded John Jay as president of congress, and in 1781 resumed his judicial position. In 1786 he was governor of Connecticut and was re-elected every year as long as he lived

HUNTLY, a small burgh of barony and market t. of Scotland, in the n.w. of Aberdeenshire, situated at the junction of the Bogie and the Deveron, 20 m. s.s.w. of Banff. In the vicinity is the ruin of Huntly castle. Pop. '71, 3,570.

HUNTSVILLE, a city in northern Alabama, United States, on the Memphis and Charleston railway, 10 m. n. of the Tennessee river. It has the usual county buildings, and a large trade in cotton and imported goods with the surrounding country. Pop. '70, 4,907.

HUNTSVILLE (*ante*), sometimes called "the queen city of the mountains," one of the most important and prosperous of the towns of Alabama. It is high up on a spur of the Cumberland mountains, and is reached by a branch of the Memphis and Charleston railroad. There are a large number of manufactories in the place, a seminary, ten churches, and two newspapers.

HUNTSVILLE, the seat of justice of Walker co., Tex., on the Houston and Great Northern railroad, 200 m. s.e. of Austin; pop. '70, 1599. There are in the place a number of important manufactories. It is also the seat of the state prison, and the burial place of gen. Sam Houston.

HUNYADY, JÁNOS (Eng. John), governor of Hungary, one of the greatest captains of his age, was born towards the close of the 14th century. Hunyady's origin is wrapped in mystery, the most accredited legend being that he was a son of the emperor Sigismund by a Wallachian lady. Hunyady and his descendants had in their escutcheon a raven—*corvus*—hence the designation of Corvinus. We find Hunyady as ban of a province s. of the Danube, distinguishing himself against the Turks, who at that time were the terror of the whole of Christendom. During the period 1437–56 Hunyady was the shield of Hungary, not only against external foes, but also against the lawless attempts of the nobles. Such was the renown of Hunyady's arms, that, after the campaign of 1444, the Turks were glad to obtain an armistice of ten years. The vacillating Vladislas I. allowed himself to be induced by the papal legate, Julian Cæsarini, to break the peace he had sworn to keep. Hunyady was defeated in the bloody battle of Várna, 1444; the king perished in the fight, as also the cardinal-legate; Hunyady was captured during his flight by the voivod of Wallachia; but upon a declaration that the whole of Hungary would rise to deliver the noble prisoner, was safely escorted to the frontier, and there set free. During the minority of Ladislaus V. (son of Vladislas I.), Hunyady was elected by the nation to be governor of Hungary. The battle of Rigómagö (1447), one of the bloodiest ever fought, was lost through the treason of the voivod of Wallachia; Hunyady had once more to go through a short captivity. But the most splendid of his deeds was the storming of Belgrade, where the monk, John Capistran, carrying the holy cross, raised the enthusiasm of the Christian warriors to such a height, that a most complete victory brought that fortress again into the possession of the Hungarians. Shortly afterwards dysentery broke out in the camp, and Hunyady, the great Christian hero, after a short illness fell a victim to the disease. Capistran, 70 years old, followed his friend into the grave two months later. Hunyady left two sons, Ladislaus and Mathias (q.v.)—the former of whom was treacherously imprisoned, and beheaded at Buda, by the very prince whom his father had so faithfully served, Ladislaus V.; the latter was given in charge to George Podiebrad (q.v.) of Bohemia.

HUPEH', one of the central provinces of China, reputed the most fertile. The great river Yangtse, recently opened to foreign commerce, flows through the s. of the province, where it receives tributaries from various lakes on either side, nearly doubling its volume of water. Area, 70,450 m.; pop. 37,370,098. Wuchang is its capital.

HUPFELD, HERMANN, D.D., 1796–1866; b. Germany, and noted as a Hebrew scholar. He was professor at Marburg and Halle, and in 1843, on the death of Gesenius, took the professorship of oriental languages. His most important work is a commentary

on the Psalms, which is considered the most thorough and masterly work of its class, and has been translated into English.

HU'RA, a genus of plants of the natural order, *euphorbiaceæ*. *H. crepitans*, a native of the West Indies and tropical America, is a tree abounding in a very acrid milky juice; with stalked, heart-shaped, acuminate, leathery leaves. The fruit is a woody capsule, of the size of a pretty large apple, very much flattened, formed of 12 to 15 *cocci*, each containing a large seed, surrounding a common axis, which separate with great elastic force. Before the use of blotting-paper became general, the capsule was generally used in the West Indies as a sand-box—whence the tree is called SAND-BOX TREE—for powdering letters with fine sand; but it was found necessary to bind it with a hoop of iron, as even after being used for years, it would sometimes burst with a report like that of a pistol. The seeds are a violent drastic purgative.

HURD, RICHARD, D.D., an eminent English prelate, was born at Congreve, in Staffordshire, Jan. 13, 1720, and studied at Cambridge university, of which he became a fellow in 1742. In 1749 appeared his first notable production, *Commentary on Horace's Ars Poetica*. In 1750, on Warburton's recommendation, he was appointed one of the Whitehall preachers. He afterwards became bishop of Lichfield and Coventry, and in 1783 declined the archbishopric of Canterbury. He died May 28, 1808. His principal works are: *Dialogues on Sincerity, Retirement, The Golden Age of Elizabeth, and the Constitution of the English Government* (1759); *Letters on Chivalry and Romance* (1762); and *An Introduction to the Study of the Prophesies concerning the Christian Church* (1772). Hallam says of Hurd, that he "has perhaps the merit of being the first who, in this country, aimed at philosophical criticism." See Hurd's works, with life, 8 vols. (1811).

HURDLES, in military affairs, consist of straight, flat rectangles of strong wicker-work, about 6 ft. long, and 2 ft. 9 in. high. They are useful in many ways, both in military and civil life, either as fencing, as barriers, or in fortification, in the construction of *hurdle-batteries*. These last were the invention of sir William Congreve, who devised them as the speediest means of throwing up earthworks; three hurdles are fastened at their ends in the form of a triangle, and the central space is filled in a short time with earth. These triangles can be constructed to any ground-plan, and with their aid, a body of soldiers can intrench themselves in a few minutes. The hurdle is composed of wattles interwoven round stakes or pickets, the latter during the manufacture being fixed upright and firmly in the ground.

HURDWAR', perhaps the most famous spot on the Ganges, stands on the right or w. bank of the river at the point where it emerges from the sub-Himalayas into the plains of Hindustan. From its position on the sacred stream, it attracts immense numbers of pilgrims for the purposes of ablution. The orthodox season comprises the end of March and the beginning of April—a great fair at the same time engrafting commerce on religion. In ordinary years, the attendance amounts to 200,000 or 300,000; but on the occasion of every 12th year, the latest having occurred in 1867, the visitors, from the commencement to the close of the festival, are stated to average about 2,000,000. The place is 1024 ft. above the sea, in lat. 29° 57′ n., and long. 78° 14′ east.

HURDY-GURDY, a very old musical instrument of the stringed kind, which, under the name of leyer, or baurenleyer, spread from its native country, Germany, over a great part of Europe. The hurdy-gurdy consists of a flat, oval-shaped sounding-board, over which the strings are stretched, with a back or bottom of the same size and shape. These are bound together by tolerably deep sides, or ribs. On one side are from ten to twelve finger-keys, for shortening the sounding lengths of the strings when required. There are four strings of gut which are put into a state of vibration by being rubbed by the edge of a small wooden wheel charged with rosin, and turned by a handle. Two of the strings are tuned in unison as a key-note, or one of them a fifth above; they are placed out of reach of the keys, and form a sort of drone-bass. The other two strings are acted on by the keys, and produce a diatonic scale of from ten to twelve notes. The hurdy-gurdy is only suited to simple music, and was used for such as had many repetitions. Its simplicity and cheapness rendered it, at one time, a favorite instrument among the peasantry of Europe. The instrument is now mostly to be seen in the hands of Savoyard boys, who play it on the streets.

HURLBERT, STEPHEN AUGUSTUS, b. S. C., 1815; practiced law in Charleston and in Illinois. In the war of the rebellion he was a brig.gen. of volunteers, and was in the action at fort Donelson. He was afterwards in service at Shiloh, Corinth, Memphis, and Meridian. In 1869 he was minister of the United States to Colombia, and in 1873 he was elected a member of Congress.

HURLBERT, WILLIAM HENRY, b. S. C., 1827; graduated at Harvard 1847, and in divinity at Cambridge. After a visit to Europe he appeared in New York in literature as a writer for *Putnam's Monthly*. After some service on the editorial staff of the *New York Times* he became one of the editors of *The World*, and with some interruptions has remained connected with that newspaper for most of the time as the principal editor. As an author, outside of his journalistic career, he has given to the world *Gan-Eden, or Pictures of Cuba*, and *General McClellan and the Conduct of the War*. Mr. Hurlbert has traveled extensively in Europe, in Mexico, and in South America.

HU'RON, one of the five great lakes of the St. Lawrence, has Superior and Michigan above and Erie and Ontario below it. It separates upper Canada from the state of Michigan, and extends in n. lat. from 43° to 46° 20′, and in w. long. from 79° to 85°, and has been estimated to contain about 20,000 sq. miles. Its surface is 584 ft. above the level of the sea; its depth about 1000 feet. Its waters are remarkable for their clearness and purity, whence the lake received from the French traders the name of MER DOUCE, or fresh sea. This vast body of water is said to contain 3,000 islands, one of them, the Great Manitoulin, or Sacred island, running parallel to almost the whole of the northern coast, which is one continuous mass of comparatively barren rocks.

HURON, a co. in e. Michigan, lying between Saginaw bay on the n.w. and lake Huron on the n.e.; area 800 sq.m.; pop. '74, 11,964. Several streams flow through it; among them Pigeon river. The surface is generally level, and the soil good, being largely covered with forests. The chief productions are wheat, oats, hay, and potatoes. Co. seat, Bad Axe.

HURON, a co. in n. Ohio, on the Vermillion and Huron rivers, intersected by three railroads. 475 sq.m.; pop. '80, 31,609. The surface is mostly level, and much of it is covered with forests. Wheat, corn, oats, wool, and butter are the main products. Co. seat, Norwalk.

HURON, a co. in w. Ontario, Canada, on lake Huron, watered by Maitland river, and traversed by the Great Western railroad; 1288 sq.m.; pop. '70, 66,165. It is a lumbering and farming region, and in some places there are valuable salt springs. Chief town, Goderich.

HURON, LAKE (*ante*), one of the five great lakes on the n. frontier of the United States, lying between lake Superior on the n.w., lake Michigan on the w., and lake Erie on the s.e. It is the third in size of the great lakes, having an area of about 21,000 sq.m., and being about 250 m. long, and 190 m. wide. It receives the waters of lake Superior through the St. Mary's river, and those of lake Michigan through the straits of Mackinaw, and empties through the St. Clair river into lake Erie. It is bounded w. and s.w. by the southern peninsula of Michigan, and n. and e. by the province of Ontario, Canada. The general direction of the lake lengthwise is from n.n.w. to s.s.e., and it is divided into two parts by the Huron peninsula and a chain of islands, of which the Great Manitoulin is the largest, which inclose altogether within Canadian territory the vast Georgian bay, and Manitoulin bay. The larger portion of the lake is in the form of a crescent, with its hollow side towards Michigan, the Michigan shore being deeply indented by Saginaw and Thunder bays. The surface is 19 ft. above the level of lake Erie, 352 ft. above lake Ontario, and 578 ft. above the sea, with occasional fluctuations as in the other lakes. Its depth is very great, averaging from 800 ft. to 1000 ft., while off Saginaw bay it is said that soundings of 1800 ft., or 1200 ft. below the level of the Atlantic, have been made without finding bottom. The waters are very clear, pure, cold, and sweet, especially in the northern part, and abound in fish, of which the whitefish is the most important. There are few harbors on the w. side, but vessels find shelter in Saginaw bay, about 70 m. n. of the outlet, and also in Thunder bay, as much further north. Presque isle is also a fair harbor, and there is good shelter under the s. side of the island of Mackinaw. A number of streams of no great importance empty into the lake. The lake is subject to violent storms, but navigation is safe from May 1 to Dec. 1. Mackinaw has long been an important post for fur trade with the Indians. Bay city, at the head of Saginaw bay, is an important lumber depot, and copper mines have been opened in the upper portions of Manitoulin bay. Excellent grindstones are cut from the sandstone near Thunder bay. It is said that not less than 3,000 islands break the surface of the lake.

HURON INDIANS. See WYANDOTS, *ante*.

HURRAH', a shout of encouragement and applause, characteristically English. It serves also as a war-cry. As an engagement at sea commences, the crews of the English vessels send up deafening hurrahs; in a charge on shore, English soldiers hurrah as they rush upon the enemy. There is something strangely exciting in this simple sound, and the combatants work themselves, as they shout, into a frenzied forgetfulness of danger.

HURREEANAH, a British district in Hindustan, in the division of Hissar, under the jurisdiction of the lieutenant-governor of the n.w. provinces; area, 3,300 sq.m.; with a comparatively scanty amount of population, consisting of Hindus and Mohammedans. The district is intersected by the canal originally constructed by Feroz Toghluk, the renowned king of Delhi. This watercourse having become nearly obliterated, was cleared out by order of the British government, and made available for the purpose of irrigation. Towards the close of the last century, George Thomas, an Irish adventurer, made a bold attempt to establish an independent principality in Hurreeanah under his own rule. He fortified the principal town, collected troops, cast cannon, and coined money bearing his own name; but being attacked by a superior native force under the command of the French adventurer Perron, he was overpowered and forced to retire. The principal towns are Hissar and Hansee.

HURRICANE. See STORMS and WIND.

HURST, a charge in heraldry representing a small group of trees, generally borne upon a mount in base.

HURST, JOHN FLETCHER, D.D., b. Md., 1834; graduated at Dickinson college; studied theology in Germany, and for 8 years after 1858 was a Methodist minister in New Jersey. In 1866 he returned to Germany and taught theology in the Martin mission institute in Bremen, and afterwards traveled in several European countries. In 1871 he was chosen professor of historical theology in the Drew theological seminary at Madison, N. J., and in 1873 was made president of the institution. Some of his works are *History of Rationalism; Outlines of Bible History; Life in the Fatherland; Lecture in Defense of St. John's Gospel;* and *History of the Church in the 18th and 19th Centuries.*

HUSBAND AND WIFE are the correct legal as well as popular terms to denote two persons married to each other. The modes of contracting marriage, with the accompanying ceremonies, and the impediments to marriage, will be more properly described under the head of marriage (q.v.), and the mode of dissolving the marriage has been already partly described under divorce (q.v.). The effects of marriage on the parties, and upon their property, will here be described, for which purpose the relation of husband and wife will be assumed to have been duly constituted. And as the effect is not the same in all parts of the United Kingdom, the laws of England and Ireland, which agree in this respect, will first be stated, and afterwards those of Scotland separately.

The effect of marriage in England and Ireland may be viewed under two heads—first, as regards the persons and the personal rights of the married persons; and secondly, as regards their property. 1. As to the person. So far as regards the person of the husband, he remains in precisely the same position as before marriage. He can sue and be sued, enter into contracts, and bind himself as fully after as before marriage, and he can even make a will, and bequeath all his property to strangers, regardless of the wife. As regards the person and personal rights of the wife, however, there is a material difference. Her person is said to be merged in that of her husband, and for many purposes they are treated as one person in the eye of the law. The meaning of that is, that the wife is under many disabilities. She cannot enter into contracts in her own name, and for most of the purposes of business she cannot be treated with as apart from her husband. Even the personal property she had before marriage, unless settled upon her by some settlement made before the marriage becomes her husband's absolutely, and he can squander it at will. The principal thing which the wife can do in the way of entering into contracts after marriage, is to order goods and necessaries for the use of herself and family and for household use; but this she does not in her own right, but merely as the agent of the husband, who is presumed by the law to give her an implied authority to that effect, and therefore the wife, when ordering goods, does not in any way bind herself, but merely her husband. As, however, this power is often abused by extravagant wives, the law qualifies the power in this way, that the goods and necessaries so ordered must be reasonable, and suited to the rank and position in life of the husband. If goods are therefore ordered which are extravagant, the husband can repudiate the contract, and return them, but he cannot keep the goods and refuse payment; if, for example, he has seen his wife wearing an expensive dress which he knows he did not himself order or pay for, if he do not at once repudiate the transaction, and return the goods, he will be held to have consented and approved of the purchase, and he cannot afterwards escape liability for the price. This position of husband and wife is taken advantage of in the lower walks of life by means of the tally system, which is the cause of much demoralization. The tallyman calls upon the wife in the husband's absence and offers her goods, which are generally in the end charged for at an exorbitant rate; but as he consents to take payment by installments, and as the wife is advised to pay them secretly, the result is that the husband's money is often squandered. These transactions being a fraud on the husband, can generally be checked if, at the first moment he becomes aware of them, the husband repudiates them; and a county court, or any other court, would give him every assistance in getting rid of any liability so incurred, if he should afterwards be sued; but it generally happens that the matter has advanced too far before it is discovered; or he has done something which is construed into an adoption of the contract; or, what is frequently the case, he ignorantly supposes that he has no remedy.

The husband, being entire master of his own actions, has the power to decide where to live, and the duty of the wife is to live with him in the same house. If she refuses to do so, and lives apart without just cause, he is not bound to support her even with necessaries. If, however, she separates from him for just cause, the case is otherwise. Though the husband is bound to maintain his wife, there is, curiously enough, no direct means in England of enforcing this duty. There are circuitous means only. The wife, for example, cannot sue the husband herself, but she has an implied authority to order necessaries, and the tradesman so supplying these can sue the husband for the price. Hence it is that when a tradesman supplies a wife, who is living apart, with necessaries, before he can be sure of recovering the price from the husband, he must satisfy himself that the wife has just cause for living separately. There are several just causes for her living apart. If the husband, for example, treats her with what is deemed cruelty in the eye of the law—as keeping a mistress in the house, starving and assaulting her—she

is entitled to leave him, and she can order necessaries at his expense from any tradesman willing to supply her. There are, however, many degrees of cruelty and ill-usage for which the wife has practically no remedy, and of which the law can take no cognizance; for the law cannot remedy a tithe of the ills of life. If the husband have the means, and yet refuses to support his wife, or what is the same thing, if he willfully refuses to work, being able to do so, and she becomes chargeable to the parish, the parish authorities can seize the goods of the husband, if any, and sell them for her support; or he may be imprisoned by justices of the peace, as an idle and disorderly person, for a month. But in such circumstances the husband more frequently deserts his wife. If he deserts her, and leaves her destitute, and a charge upon the parish, he may then be treated under the vagrant act as a rogue and vagabond, and imprisoned by justices of the peace in the house of correction for three months. If the desertion continue for a period however long, it is no ground in England for a divorce; but if it is coupled with adultery, and continues two years, it will be so. It sometimes happens that after a husband has deserted his wife, she maintains herself by her own exertions, and acquires property; in such a case, her earnings (unless the marriage took place after 1870) belong to him, though the wife might in all cases get a protection order from justices of the peace, which excludes him and his creditors. Stats. 20 and 21 Vict. c. 85, sec. 21; 21 and 22 Vict. c. 108, sec. 6, 7, 8; 33 and 34 Vict. c. 93, sec. 1.

As regards crimes committed by a wife, she is in general liable to be punished for these in the same way as if she were unmarried. But there is a peculiarity as regards crimes committed by the husband and wife jointly. If the crime be treason or murder, both are punished precisely as if they were unmarried. But in all the lesser crimes, the theory as well as the practice is, that if the wife was a party to the crime, and committed it in her husband's presence, she is presumed by the law to have so acted under the compulsion or coercion of her husband, and is acquitted as a matter of course. And so favorable is the law on this ground to married women who commit crimes, that, in the absence of any direct evidence one way or the other as to where the crime was committed, it will still be presumed that the wife acted under this marital coercion, and so she escapes punishment. Another curious anomaly arising from the maxim that husband and wife are one person, is, that a wife cannot be convicted of stealing her husband's goods. If she abscond with his property, however valuable, she cannot be punished. But this rule is again qualified by the circumstance, that if she commits adultery, and afterwards absconds with the adulterer, both taking away the husband's goods, the adulterer may be convicted of the larceny, though it is doubtful if she is in that case liable to any punishment. And where the third party has not in view any adultery with the wife, but joins her in taking away the husband's goods, in many cases neither he nor the wife can be punished criminally.

Husbands and wives may be witnesses for or against other parties in all civil cases, i.e., actions and suits relating to debts, contracts, and wrongs which are not crimes, and in all inquiries of a civil nature. So when the husband is himself a party in a civil action, his wife may be compelled by the opposite party to be a witness; but in all such cases neither husband nor wife can be compelled to disclose any communication made to him or her by the other spouse during the marriage. As regards all criminal proceedings instituted against either husband or wife, the other spouse is neither competent nor can be compelled to be a witness; but where the husband and wife are not the accused, but the prosecuting parties, then, inasmuch as the crown is presumed to be the prosecutor, and they are not parties, they may be both witnesses, subject to the qualification as to not being bound to disclose communications made by and to each other during marriage. There is an exception also to the rule that neither can be a witness against the other in criminal proceedings—viz., where the wife charges her husband with an assault or other crime of greater degree upon her person, she is in that case only a competent witness against him, for otherwise the crime might go unpunished. Moreover, in all proceedings instituted in consequence of adultery of the husband or wife, neither of the married parties is competent or can be compelled to be a witness.

2. As to the property of the married persons. As regards the husband, he still remains sole owner of his property, real and personal, and can do what he likes with it; and he may, as already stated, by will devise and bequeath it all to strangers, regardless of the wife. He can also sue and be sued as before, irrespective of his wife. But as regards the wife, the case is different. Owing to her incapacity to contract or even to hold personal property independently of her husband, she can neither sue nor be sued except where she has separate property settled upon her, as afterwards explained. If she had personal property before marriage, the whole, in marriages before 1870, was the sole and absolute property of the husband immediately after the marriage, if there is no marriage settlement. All debts which were due to her before marriage also become after marriage debts due to him, provided he chooses to reduce them into possession, and sue for them. As a general rule, therefore, the wife could not, unless married after 1870, earn and enjoy her earnings separately; but this, as well as legacies coming to her, are now, by the act 33 and 34 Vict. c. 93, made the rule in all cases, and he is not liable for the wife's debts contracted before marriage, but a settlement may still vary the rule. As regards persons married before 1870, the old rule remains, that she could not sue in her own right. Hence, in cases where a debt was due to her before marriage,

or the money claimed had been earned by her during marriage, both she and her husband may sue for it, or he alone must sue for it, according to circumstances. In like manner, when the wife was in debt before her marriage, the husband, who in effect married her debts also, must be sued jointly with her; and so, if she committed some wrong, as a slander or assault, the husband must be sued jointly with her; but where she merely ordered goods which were supplied to the husband, he alone is liable, and he alone can be sued. When the wife was once sued along with the husband, both of them could be imprisoned; but the wife was immediately discharged, as a matter of course, on application to a judge, provided she had no separate property of her own out of which the debt was payable. The old rule as to the wife's personal property becoming the husband's absolutely after marriage, suffered qualification when such property consisted not of money or chattels, but of what are called chattels real, such as leases and mortgages. In such a case, they become so far the property of the husband, that he can sell them during his life, but he cannot bequeath them by will; and on his death they remain hers, while on her death they become his. Again, where the wife's personal estate before marriage consisted of mere rights of action or debts due to her, they were so far his that he could at any time sue for them, and so reduce them into possession, and make them his own absolutely, but could not bequeath them by will: and if he did not sue for them in his lifetime, they survived to the wife after his death. As regards the wife's real estate—i.e., her lands and houses held in freehold—the husband does not acquire these absolutely by the marriage, but he thereby becomes entitled to a life-estate in them. He cannot sell the property, though he may sell his own life-estate in it. On the other hand, though the real estate still continues to belong to the wife, she cannot sell it, like an ordinary owner, unless she separately acknowledges the deed of sale, which is done by her going before a commissioner or a judge, who examines her in private, and explains the nature of the deed, and sees that she understands its purport, and that she acts freely, without the coercion of the husband.

On the death of one of the married parties, the property is disposed of as follows: if the husband dies, his will may, as already stated, dispose of his whole property to strangers, irrespective of the wife, and she may be left entirely destitute in consequence. But there are some things his will cannot take away from her, as, for example, her leases, separate property, etc., and her real estate. To these may be added her paraphernalia, which consists of her personal apparel and jewels; but even these will be taken by her husband's creditors, if there is a deficiency of assets. If the husband die without a will, the law is more liberal to the widow: she is entitled to one-third of the husband's personal estate absolutely, and not merely to a life-interest; she is also entitled to dower out of her husband's real estate, i.e., to a life-interest of one-third of the whole real estate which belonged to him. This right of dower, however, can in general be defeated by the husband's will. When the wife dies before the husband, he becomes entitled to nearly all her personal estate, of whatever description, even though she left children of the marriage; and it must be recollected that she can in general make no will which has any effect, if the husband chooses to repudiate it. As regards the wife's real estate, if a child has been born, who might by possibility have inherited her real estate, then the husband has, by the courtesy of England, an estate for life in the whole of such real estate; but if no child has ever been born, the real estate goes to the wife's heir-at-law, or if none, to the crown.

The common law of England has been often considered, especially of late years, as unjust towards women, in subjecting them too much to the caprice of their husbands. There are, however, several ways of avoiding this, but they are only available, as will at once be seen, to the rich. The most effectual way of preventing the husband having powers so absolute as the law gives him, is by executing a marriage settlement before marriage. By means of a settlement, not only all the property which the wife has before marriage, but also all which she expects to have during marriage, may be settled upon her to her separate use, and put entirely out of the power of the husband. This is done by the agency of trustees, who hold and manage her property as their own, keeping the husband at arms' length, and yet she has almost the same power of acting independently as if she were not married: she can draw her rents, keep her bank-account, enter into contracts, and bond her separate property, and also execute her will, as if she were a man. Sometimes the husband and wife both settle their property by the same settlement; or if the wife has no property, the husband may settle his upon her in the same way. She is in that case generally allowed a certain sum per annum as pin-money, to spend upon her personal adornment; and by means of her trustees, she can sue her husband for this sum, if not punctually paid. Sometimes, by the marriage settlement, if the husband had no money, the wife's money is settled partly upon him, so that he has a certain allowance per annum; but in the event of his becoming insolvent or bankrupt, the money is not to go to his creditors, but to remain for the wife's use. In short, there is practically no limit to the variety of mutual arrangements, by means of a marriage settlement, for providing against the possible hardships of the common law. It is on the same principle that, in some cases, the court of chancery has interfered to prevent the husband acquiring so absolute an interest in the wife's property as the common law gives him. But a great step towards emancipating married women's property from their husband's power was achieved in 1870 by the act 33 and 34 Vict. c. 93, which, as

already stated, made the wife's earnings and legacies her separate property, and enabled her to make deposits in savings banks, and in the funds, and to insure her own or her husband's life for her own exclusive benefit, and so that she can sue in her own name for her separate property. This act has some defects which the legislature must sooner or later remedy and extend, for the better protection of women, and unremitting efforts have been used for this purpose.

When a marriage is once contracted, the parties cannot of themselves, or by any arrangement they can enter into, put an end to it; nothing can do this but a divorce, or the death of one of the parties. It is a delusion not uncommon among the working-classes, that if one of the parties runs away or disappears, the marriage is at an end, and the party left behind may, at least after a time, marry again. This is, however, not the case. It is true, that if one of the parties has not heard of the other for seven years, and has reason to believe that that other is dead, the former cannot be convicted and punished for bigamy in marrying again. But this is merely an excuse for escaping the usual punishment; the second marriage only remains good if the lost party is really dead, or never turns up again. If at any time, however remote, the party supposed to be dead returns, the first marriage still remains good, and the second bigamous marriage becomes a nullity, and the children born of it, if any, are bastards, so that so long as both parties live, the only way of dissolving the marriage, so as to permit either to marry again, is a divorce, which can be obtained only on certain grave grounds. There is an intermediate state, called *judicial separation* (q.v.), which can be brought about for certain grounds less than what would warrant divorce. But though a wife judicially separated may enter into contracts, and is, as regards her dealings, much the same as an unmarried woman, she is still a wife, and cannot marry again; and if the parties are living separate by mutual agreement, they are nevertheless married, and have most, though not all, of the rights of married persons.

Scotland.—The law of husband and wife in Scotland as regards their personal rights and disabilities, and the property during the marriage, does not substantially differ from the law of England and Ireland, but the following points may be noticed. As regards their persons and personal rights and crimes, the law is the same. It is often said that in Scotland the movable property of both husband and wife become a kind of joint-stock property, called *goods in communion* (q.v.); but this phrase has no meaning except with reference to the principle of the division of the property after the death of one of the parties, and the dissolution of the marriage. The husband is, as in England, entire master, except that he cannot on death-bed bequeath more than a share of the property away from the wife. The wife's movable property becomes the husband's, and her heritable property remains subject to the husband's life-rent. When she disposes of her heritable property, she must ratify the deed by going before a magistrate, and acknowledging that she acts of her own free will. When the husband deserts her, she may, as in England, obtain a judge's order to protect her earnings and moneys; and she has a preferable right to a reasonable provision out of any property to which she may succeed. (Conjugal rights amendment acts, 1861 and 1874.) By the married women's property (Scotland) act, 1877, the produce of a wife's industry or skill is excluded from the rights of her husband, and his liability for her antenuptial debts is restricted to the amount she brought into the marriage. A wife has, in Scotland, the power to bind her husband for necessaries; but the husband can, by a process of inhibition, give notice to tradesmen not to supply her at his expense, and this notice will be binding on all the queen's subjects. No such notice in England would have so strong an effect: but even in Scotland such a notice as inhibition does not prevent the wife ordering necessaries, if not otherwise supplied. A rich wife is bound, in Scotland, as in England, to maintain her husband out of her separate estate. In Scotland, as in England, the rights of the parties may be varied by an antenuptial contract or marriage settlement; but there is less need for it, for the common law makes a provision for the wife in spite of her husband, since he cannot by will bequeath away from her more than one-third or one-half of his movable property respectively, according as there are children or no children. See GOODS IN COMMUNION, WILL. In Scotland, as in England, the married parties may also execute a post-nuptial contract, which will be binding if the husband was solvent at the time of executing the deed; but though in England it will be in that case valid both as against wife and children and creditors, yet in Scotland it will bind the wife and children only if they thereby get a better provision than they would have been entitled to independently of any deed, or at least something which they accept as equivalent. And, as a general rule, nothing can be done after marriage by the parties so as to settle the property on either party, if the effect is to defeat their then creditors. The Scotch widow's terce corresponds to the English widow's dower, and the rule as to the paraphernalia is not substantially different. The law as to the dissolution of the marriage and bigamy is the same in Scotland, though the grounds of divorce are more liberal in Scotland. See DIVORCE. Paterson's *Compendium of English and Scotch Law.*

HUSBAND AND WIFE (*ante*).—A little more than thirty years ago the legal status of husband and wife in respect to each other and to society, in all or nearly all the states of the American union, was nearly the same with that in England. Under the common law, wives were often subjected to great hardship. Half a century ago the

public attention was called by a few earnest people to the essential injustice of these long-established doctrines, the key to which is found in the maxim that the legal existence of the wife is merged in that of her husband. The agitation, though discountenanced and ridiculed for a time, took fast hold upon the public conscience, and found expression in numerously signed petitions to the legislatures for a reform of the obnoxious laws. While the claim of the agitators that women should be permitted to vote and be made eligible to office was lightly regarded, conscientious legislators would not refuse to listen when wives and mothers besought them to redress odious and inhuman abuses. Women who had made a study of the subject were accorded a hearing before legislative committees. New York was the first state to respond to the demand for reform, but the example was followed by others in rapid succession, until now the common law doctrine that a wife's legal existence is merged in that of her husband is regarded with universal disfavor as a relic of barbarism. The laws of the states differ in some respects from each other, but as a general rule the real and personal property possessed by a woman at the time of her marriage, or which she may acquire thereafter, remains her own, free from any interest of the husband or any claim of his creditors. In some of the states, but not in all, she is permitted to convey her property by deed, or to bequeath or devise it by will. In New York and a few other states, she is allowed to manage her property as if single, to make contracts concerning it, to engage in any trade or business, to appropriate her own earnings, to sue and be sued, and to maintain actions in her own name for injuries done to her person, property, or character. As truly, as wittily said, that in the eye of the common law husband and wife are one, and that that one is the husband; but under the new legislation the wife has the same standing before the law as her husband. In the western and southern states the wife has a secure interest in the homestead, and cannot be dispossessed without her consent. The new legislation has not changed the common law presumption that it is the husband's duty to support his family, to furnish a home for his wife, and provide her with such means of subsistence as are suitable to his station in life. As a general rule it is still the right of the wife to procure the necessaries of life upon his credit. She may leave him, if she chooses, and there is no law to compel her to return; but in that case, her right to a support from him will cease. If she be enticed away or seduced, the husband may recover for any pecuniary damages thereby incurred. The old rule, that he is responsible for any crime committed by her in his presence and by his direction, remains in force. In many of the American states husbands and wives may be witnesses against each other, except as to facts communicated in marital confidence.

HUSBANDRY, PATRONS OF. See GRANGE, *ante*.

HUSBANDRY, SERVANT IN. Under a variety of acts, agricultural servants could be sentenced to imprisonment by a justice of the peace for breach of the contract of service. This liability was abolished in 1875, and husbandmen are now entitled to the remedies provided by the employers and workmen act of that year.

HUSBANDS, HERMAN, d. 1794; prominent in the American revolution; member of the Pennsylvania legislature, and one of the leaders of the "regulators in North Carolina." He was an associate of Albert Gallatin and other patriots, but after the peace was compromised in the whisky insurrection in Pennsylvania and imprisoned.

HUSCH, a t. of Moldavia, on a feeder of the Pruth, 40 m. s.e. from Jassy. It is the capital of a district. Here the treaty between the Russians and Turks was signed in 1711. Pop. about 12,000.

HUSKISSON, WILLIAM, an eminent English statesman, was b. at Birch Moreton, in Worcestershire, Mar. 11, 1770, and in 1783 was sent to Paris to study medicine. He took part in the storming of the Bastile, and as a member of the club of 1789, attracted attention by a number of speeches on subjects of political economy. In 1792 he returned to England, received a subordinate appointment under the tory government, and formed an intimate acquaintance with Pitt and Canning. In 1795 he was selected by Dundas, the war minister, to be first under-secretary; and sat in parliament for Morpeth. He subsequently held several offices under Pitt, with whom he retired in 1801, and on the dissolution of parliament in 1802, lost his seat in the house of commons. In 1804 he was returned for Liskeard, and was appointed secretary of the treasury in the new Pitt cabinet. On Pitt's death, however, in 1806, he lost this office, but was restored to it by Mr. Percival in 1807. He sat for Harwich, 1807–12; Chichester, 1812–23; and Liverpool, 1823–30. In 1814 he was chief commissioner of the woods and forests; in 1822, president of the board of trade; in 1827, secretary of state for the colonies; and in 1828, secretary of state for foreign affairs. But this office he resigned, and retired from the ministry the same year. Through his exertions the old restrictions on the trade of the colonies with foreign countries were removed. He also obtained the removal or reduction of many import duties, considerable relaxation of the navigation laws, and is allowed to have been the great pioneer of free trade. He received fatal injuries at the opening of the Liverpool and Manchester railway, Sept. 15, 1830, and died the same evening. A collection of his speeches was published in 1831. Both from the comprehensiveness of the views which they exhibit, and their fullness of accurate details, they are interesting to the student of political economy.

HUSS, JOHN, the Bohemian reformer, whose name is associated with that of Jerome of Prague (q.v.), both on account of the work which they wrought and the death which they suffered, was b. in 1373 at Hussinecz, near Prachaticz, in the s. of Bohemia. He studied at the university of Prague, where he soon made great progress in the branches of learning most valued in that age, took his degree of master of arts in 1396, and began to lecture publicly in 1398. In 1402 he became preacher in the Bethlehem chapel in Prague, and labored with the greatest earnestness for the instruction of the people, and in the discharge of all his clerical functions. As a preacher he was greatly esteemed both by the common people and by the students; whilst as confessor to queen Sophia he obtained access to the court. At this time he became acquainted with the writings of Wickliffe, which exercised a great influence over him. The monks and clergy were of course violent enemies to Huss, as he denounced, with continually increasing boldness, their corruptions. Archbishop Sbinko burned the writings of Wycliffe in 1410, in compliance with a brief of pope Alexander V., and complained to the pope of Huss as a Wycliffite. Hereupon he was summoned to Rome; but he did not go, and the combined influence of the people, the court, and the university, compelled the archbishop to remove a prohibition which he had issued against his preaching. But in 1412, pope John XXIII. having published a bull of indulgence in order to a crusade against Ladislaus, the excommunicated king of Naples, whose kingdom the pope claimed as a papal fief, Huss boldly raised his voice against the whole procedure as unchristian, whilst Jerome of Prague also stood forth to condemn, in the strongest manner, both the bull and the vendors of indulgences. An interdict against Huss, in 1413, was the consequence. Huss, however, appealed from the pope to a general council and to Christ, and wrote a book, *On the Church*, in which he condemned the abuses of the papacy, and denied the unconditional supremacy of the Roman pontiff. Thinking himself no longer safe in Prague, he now retired to his native place, where he preached the gospel with great power. In 1414 he went to Constance to the general council, summoned thither, indeed, on a charge of heresy, but under the protection of king Wenceslaus, and having a safe-conduct from the emperor Sigismund. Having reached Constance Nov. 3, he was, on the 28th of the same month, apprehended in spite of the remonstrances of the Bohemian and Polish nobles. His trial was conducted with little regard even to the appearance of equity. July 6, 1415, thirty-nine charges were exhibited against him, some of which he acknowledged as exhibiting his doctrine, whilst others he utterly denied. Being required to recant his alleged errors, he refused to do so until they should be proved to be errors. He and his writings were now condemned to the fire, and in spite of his safe-conduct, the sentence was carried out on the same day, and the ashes of the martyr were thrown into the Rhine. See Palacky's *Gesch. von Böhmen.*

HUSSAR', a light-cavalry trooper, dressed in a loose jacket, with other articles of attire easy in set, and a fur cap; armed usually with a saber and pistol. The idea of these troops, now in every army, came originally from Hungary. There were 13 regiments of Hussars in the British army in 1877.

HUSSITES, the followers of Huss (q.v.). Honoring him and Jerome of Prague as martyrs, they despised the decrees and anathemas of the council, and took terrible revenge on the priests and monks. The symbol of their confederacy was the cup, the use of which in the Lord's Supper they extended to the laity, as James de Misa had already done with the approbation of Huss. In 1417 king Wenceslaus was constrained to grant them the use of many churches. After his death, Aug. 13, 1419, the majority of the states refused to acknowledge his brother, the emperor Sigismund, who had broken his safe-conduct to Huss. And the papal instructions to the cardinal legate, John Dominico, requiring him to employ violent measures for the conversion of the Hussites, an insurrection ensued, and the war began which is known in history as the Hussite war. Convents and churches were reduced to ashes, and priests and monks were slain. The Hussites divided into two parties—the *Calixtines* (q.v.), and the *Taborites* (q.v.). See *Huss et la Guerre des Hussites*, by Ernest Denis (1879).

HU'STED, JAMES W., b. N. Y., 1833; graduated at Yale and was admitted to the bar in 1857. After filling a number of local offices he was chosen to the legislature, and in 1847 was speaker of the assembly.

HUSTINGS (Ang.-Sax. *husting*, a place of council), a place or platform where members of parliament are formally proposed or nominated for election.

HU'SUM, a t. of Prussia, in the province of Sleswick-Holstein, and 22 m. w. of the town of that name, is situated on the coast of the North sea, at the mouth of a small river. It was formerly strongly fortified, and possessed many ships. Pop. '75, 5,765, who manufacture leather and tobacco, and carry on distilleries and breweries, and some trade in wool and cattle.

HUT, in army affairs, is a wooden structure, more or less rough in its details, for the housing of troops. It is substituted very often for the tent, when the sojourn in a camp or cantonment is likely to be of consideration, as, for instance, through a winter—a hut, however rude, which is wind and water-tight, being as superior in comfort to a tent as the latter is to the open air. Huts may be made of almost any size, and are sometimes for one officer; at others, for as many as 100 men. The principal hut encampments at

present in the United Kingdom are at Aldershot, Shorncliffe, Colchester, and the Curragh of Kildare; in British North America, hut-camps are situated at intervals of a day's march on the route from New Brunswick to Quebec, and the troops who made that winter-march in 1861 to 1862 found their shelter truly welcome.

As the hut is as useful to the settler in a wild country as it is to a soldier, we give some of the particulars of their manufacture in different forms. Huts are of four sorts: 1. The *log* hut; 2. The *framed* hut; 3. The *pisé* hut (of tempered clay).

The *log hut* is formed of rough logs or trunks of trees, laid crosswise in tiers to the required height, the angles being formed by a notch on each side of the log, about one-third of its diameter in depth, and a few inches from the extremity. The space between the logs is then made water-tight and air-tight by a stuffing of clay, wattles, sallows, or small bundles of twigs. Within, the joints should be lined with laths, or the whole interior may be boarded with inch-planks, if such are attainable. The roof should be supported by a scantling (see ROOF), and may consist of overlapping boards, or boards laid flush and shingled, or laths and shingles, or even birch-bark alone. The door is usually ledged, and there are one or two windows, with glazed sashes and shutters. These should be made by regular carpenters, and taken to the place of building ready for use. A hut thus formed makes a snug habitation, and will last for many years; exclusive of the sashes, two men can erect, in about a week, a hut of rough logs which shall be sufficiently large for their residence—that is, with an interior area of about 15 ft. by 10 feet.

When circumstances permit the logs are occasionally squared, which enables them to be fitted more accurately to each other, and adds, of course, to the solidity and finish of the whole structure, as well as to its durability. In this case the corner logs, instead of crossing each other, are joined by a dove-tail, or by cutting the end of each to an angle of 45°.

The *framed* hut has the advantage over the log hut of allowing more exactness of finish and from its lightness and portability being easily transported to any place where logs for hut-building might not be forthcoming. It consists of a strong framework of squared wood, properly fitted together, and covered with overlapping planks or weather-boards. The pieces should be sawn to the proper size, fitted to each other, and numbered; then packed together in small compass for conveyance to the intended site, where the structure can soon be erected. No one piece need exceed 11 ft. in length, 6 in. in breadth, and 2 in. in depth. The uprights should not be more than from 15 in. to 18 in. apart, and should be firmly held by diagonal tie-rods. The first step is to carefully level the ground on which the hut is to stand, and if a dwarf-wall of stone or brick, 8 or 10 in. high, can be built round, so much the better. On this ground or wall a rectangular frame of thick wood (say 6 in. by 3) must be laid as a basis for the framework; on this latter the uprights are placed, the binding tie-rods fixed, and the cap-sill, corresponding to the frame below, placed above all, every joint being carefully mortised and tenoned. The weather-boards can now be nailed on the outside, and when the roof is put on, the hut is complete. The breadth should not, for stability, exceed 16 ft.; and when the hut is of any considerable length, cross-beams should be thrown from side to side at the top. The roof should be made of ordinary scantling, as described under ROOF. It is usually estimated that one of these huts, 30 ft. long, 16 broad, and 10 high, makes a good barrack-room for 20 soldiers. The camps at Aldershot and the Curragh are mainly formed of framed huts. Where extra warmth is desired, the spaces between the uprights are built up roughly with bricks, burned or unburned.

Pisé huts, common in the s. of France, and very useful where wood is scarce, as well as very comfortable, are walled with blocks of clayey earth, rammed with great pressure into wooden molds until they assume the forms of stones. These are laid one above each other much as stones themselves would be by a mason, and the wall so formed is both durable and sightly.

The most critical operation for the non-professional hut-builder is roofing. This is usually of thatch, shingles, paper, or felt, if lightness be an object; and of stones, bricks, or tiles, if the walls be calculated to bear their pressure.

HUTCHESON, FRANCIS, a distinguished philosopher of last century, was the son of a Presbyterian minister in the n. of Ireland, where he was born in 1694. He studied for the church at the university of Glasgow, but shortly after the completion of his theological course, he was induced to open a private academy in the city of Dublin, which proved highly successful. In 1720 he published his *Inquiry into the Original of our Ideas of Beauty and Virtue*, etc., which was the means of introducing him to the notice of many influential personages, such as lord Granville, then lord-lieutenant of Ireland, archbishop King, primate Boulter, and others. This work was followed, in 1728, by his *Essay on the Nature and Conduct of the Passions;* and in the year after, he was appointed professor of moral philosophy in the university of Glasgow. Here he died in 1747. His largest and most important work, *A System of Moral Philosophy*, was published at Glasgow in 1755 by his son, Francis Hutcheson, M.D., with a preface on the life, writings, and character of the author, by Dr. Leechman, professor of divinity in the same university. As a metaphysician, Hutcheson may be considered a pioneer of the so-called "Scotch school." From the period of his lectures, according to Dugald

Stewart, may be dated the metaphysical philosophy of Scotland, and, indeed, the literary taste in general, which marked that country during the last century, although, as Stewart acknowledges and Hamilton shows, traces of the Scotch philosophy appear in earlier writers. But it is as a moral philosopher, rather than as a metaphysician, Hutcheson shines. His system is, to a large extent, that of Shaftesbury, but it is more complete, coherent, and clearly illustrated. Hutcheson is a strong opponent of the doctrine that benevolence has a selfish origin. The faculty by which moral distinctions are recognized, Hutcheson (after Shaftesbury) terms a *moral sense*. See ETHICS.

HUTCHINS, THOMAS, 1730–89; b. N. J.; at an early age entered the British military service and was engaged in Indian wars. He was in London in 1779 and was imprisoned on suspicion of favoring American independence. Escaping by way of France, he came to Charleston and took service under gen. Green in the continental army. He was favorably known as a topographer and a maker of maps.

HUTCHINSON, a co. in s.e. Dakotah, on Dakotah river; 432 sq.m. Formed since the census of 1870. It is generally level, and there is very little timber. Co. seat, Olivet.

HUTCHINSON, ANNE, a religious enthusiast, of American celebrity, emigrated from Lincolnshire, England, to Boston, Massachusetts, in 1636. Living in a community prone to religious excitement, she claimed to be a medium of divine revelations, and held meetings for women, in which she held forth Antinomian doctrines. Great controversies arose, and a synod was called, in which her teachings were condemned, and she was banished from the colony. She and her friends now obtained from the chief of the Narragansetts liberty to reside in Rhode Island, where they set up a community on the highly commendable principle, that no one was to be "accounted a delinquent for doctrine." After the death of her husband (who shared her opinions), she removed to a Dutch settlement, in the colony of New York, where, in 1643, she and her whole family of 15 persons were taken prisoners by the Indians, and all but one daughter barbarously murdered.

HUTCHINSON, JOHN, 1616–64; b. England; represented Nottingham in parliament, and was a member of the court for the trial of Charles I., concurring in the sentence. He was arrested, and imprisoned, and died while in confinement. A memoir of his life was written by Lucy Hutchinson, his wife, and published in London in 1806.

HUTCHINSON, JOHN, an English theological writer, b. 1674 at Spennithorne, in Yorkshire. He was for some time steward of the household of the duke of Somerset, and left his service to devote himself to his religious studies, the duke procuring for him a sinecure appointment of £200 a year from government. In 1724 he published the first part of a work called *Moses's Principia*, in which he defended what he regarded as the Mosaic cosmogony, and assailed Newton's theory of gravitation. He continued to publish a succession of works till his death, which took place on Aug. 28, 1737. His religious system is best exhibited in his *Thoughts concerning Religion*. The leading principle of it is that the Holy Scriptures contain the elements not only of true religion, but of all rational philosophy, which, however, was to be derived only from the original Hebrew; and it, for that purpose, was subjected to strange critical or rather fanciful processes. His works at one time exercised a considerable influence. His followers were called HUTCHINSONIANS, and among them—strange as it may seem—were persons of considerable learning and celebrity.

HUTCHINSON JOHN, 1674–1737; b. England; remembered as an opponent of Newton's theory of gravitation. He published several works containing an interpretation of the Hebrew Scriptures.

HUTCHINSON, THOMAS, 1711–80; b. Boston, graduated at Harvard, and began the practice of law. He was several times elected to the general court, and for three years served as speaker. In 1760 he held at one time four offices: judge of probate, councilor, chief-justice, and lieutenant-governor. In the time of the stamp act he favored the British government, for which his house was sacked and many valuable manuscripts relating to the history of Massachusetts were destroyed. In 1769 Hutchinson was made governor of the colony, but he did not receive his commission until 1771. It was proved by Franklin that he had displayed duplicity in his course with regard to the relations of Great Britain and the colonies. In 1774 he returned to England, where he died, having been pensioned by the government. He published *The History of the Colony of Massachusetts Bay* (down to 1750), and *A Brief State of the Claims of the Colonies*.

HUTTEN, ULRICH VON, famous in the history of the reformation, was descended of an ancient and noble family, and was born at the family castle of Steckelberg, in the electorate of Hesse, April, 1488. When he was ten years of age, he was placed in the monastery at Fulda; but disliking this mode of life, he fled to Erfurt in 1504, where he associated with scholars and poets. He then lived at various places in northern Germany till about 1512, when he went to Pavia to study law. After passing several years in Italy, he returned to Germany and made himself conspicuous by his publications, especially those concerning the affair of Reuchlin and the Dominican Hoogstraten, in Cologne, in which he came to the support of Reuchlin, and displayed no small

learning and great power of satire. He again went to Italy in 1515, to take the degree of doctor of law, and returned to his native country in 1517. He was crowned with the poet's laurel crown at Augsburg, and the emperor Maximilian conferred on him the honor of knighthood. In the same year he edited a work of Laurentius Valla, found in a convent, *De Falsâ Creditâ et Ementitâ Donatione Constantini Magni*, and in 1518 accompanied Albert, archbishop of Mentz, to the diet of Augsburg, where Luther had his famous conference with Cajetan. Subsequently, he established a small printing-press of his own, and employed himself in writing and disseminating pamphlets fully exposing the arrogance and wickedness of the Romish clergy. The archbishop Albert denounced him to Rome, whereupon he entered into an immediate and avowed connection with Luther, whom he had hitherto despised. At this time, also, he began to write in the German language, instead of Latin. Persecuted by his enemies, he availed himself of the protection of Franz von Sickingen, but was soon forced to flee. From this time Hutten was compelled to adopt a wandering life, and died Aug. 31, 1523, in the isle of Ufenau, in the lake of Zürich. Hutten was bolder and more open in the expression of his opinions than almost any man of his age. He did much to prepare the way for the reformation, and to promote it. It may be attributed to him as a fault, that he was too reckless of consequences, and not sufficiently tender in dealing with things that had become venerable in the eyes of many; but he was a man who feared nothing, even when almost all his friends trembled. He was a master of the Latin language. He left 45 different works, of which a collective edition was published at Berlin in 1821–27, in 6 volumes. Hutten had a share in the *Epistolæ Obscurorum Virorum* (q.v.). See life of Hutten by D. F. Strauss (1858), English translation (1874).

HUTTON, CHARLES, an eminent mathematician, was the son of a superintendent of mines, and was born at Newcastle-upon-Tyne, Aug. 14, 1737, and in 1755 became teacher in a school at Jesmond, and afterwards at Newcastle, till 1773. During this period, he published his *Treatise on Arithmetic and Book-keeping* (1764); *Treatise on Mensuration* (London, 1771); and *Principles of Bridges, and Mathematical Demonstration of the Laws of Arches* (Newcastle, 1772). In 1773 he was appointed to the professorship of mathematics at the royal military academy, Woolwich, and in Nov., 1774, was elected a fellow of the royal society. Soon after this, he was selected to perform the necessary calculations for determining the density of the earth from Dr. Maskelyne's observations on Schiehallion, and his report was published in the *Philosophical Transactions* for 1778. In 1779 he received the degree of LL.D. from the university of Edinburgh. He died Jan. 27, 1823. Hutton's most important works are—*Tables of Products and Powers of Numbers* (London, 1781); *Mathematical Tables* (London, 1785); *Mathematical and Philosophical Dictionary* (London, 1795); *Course of Mathematics* (London, 1798–1801); and *Recreations in Mathematics and Natural Philosophy* (4 vols. London, 1803); the last being a most interesting and instructive work. Besides these, he regularly contributed mathematical papers to the *Ladies' Diary*, of which he was for some time editor, and also to the *Philosophical Transactions*. His biography has been written by Dr. Olinthus Gregory.

HUTTON, JAMES, a celebrated geologist, was the son of a merchant in Edinburgh, and was b. there June 3, 1726. He studied in his native city, and afterwards at Leyden, where he took the degree of M.D. He devoted himself, however, not to the medical profession, but to agricultural pursuits and to the science of chemistry, from which he was led to mineralogy and geology. He contributed much to the improvement of agriculture in Britain. He made some chemical discoveries, and is the author of a theory of the earth and of a theory of rain. His theory of rain has been since acknowledged by men of science as generally correct, although at first it met with some opposition. His theory of the earth has for its distinguishing feature the supposed agency of a central heat, by which the elevation of strata and many other phenomena are accounted for, and some parts of it may be regarded as now also substantially admitted by all geologists, although for a time it was combated by the followers of Werner, who sought to explain everything by aqueous solution and crystallization. Dr. Hutton was indeed too extreme in his theoretical views, and some of his followers were still more so. He was, however, not only a theorist, but an observer, and his discovery of granite veins is of no small importance in the history of geology. He died March 26, 1797.

HUXLEY, THOMAS HENRY, naturalist and comparative anatomist, b. at Ealing, Middlesex, in 1825, was educated at the school in that town, and afterwards studied medicine in the medical school of Charing Cross hospital. In 1846 he entered the medical service of the royal navy, and did duty at Haslar, under the late sir John Richardson, until the winter of the same year, when he was appointed assistant-surgeon on board the *Rattlesnake*. This vessel, commanded by capt. Owen Stanley, was commissioned to survey the intricate passage within the Barrier Reef skirting the eastern shores of Australia, and to explore the sea lying between the northern end of that reef and New Guinea and the Louisiade archipelago. Imbued with a passion for natural history, Mr. Huxley devoted himself with zeal and intelligence to the study of the numerous marine animals collected from time to time during the survey, and made them the subjects of scientific papers, which he sent home, diffident as to their

value. They were published, however, by the royal society and the Linnæan society, and made their author known, while yet a young man, to the naturalists of Europe. Towards the end of 1850, the *Rattlesnake* returned to England, and Mr. Huxley had the gratification to find that his paper *On the Anatomy and Affinities of the Family of the Medusæ* had been published in the *Philosophical Transactions.* Thus encouraged, he set to work to arrange his large accumulation of facts and observations, with a hope (which was disappointed) that the admiralty would contribute towards the cost of their publication. In 1851 papers on other branches of the same subject were printed in the *Philosophical Transactions;* and in the same year Mr. Huxley was elected a fellow of the royal society. In 1852 one of the two royal medals annually given by the society was awarded to him, in recognition of the scientific value of the papers above referred to. In those papers, much light was thrown on the structure of a number of animals before unknown, or but little known, to British naturalists. In 1854 Mr. Huxley was appointed professor of natural history in the royal school of mines, in place of prof. Edward Forbes, and, among his lectures in that institution, has delivered courses to working-men with beneficial results. In 1857, jointly with Dr. Tyndall, he wrote a paper, *Observations on Glaciers,* which was printed in the *Philosophical Transactions;* and in the following year he delivered the royal society's Croonian lecture, *On the Theory of the Vertebrate Skull,* in which a highly important anatomical question was discussed. In 1859 his large work on *The Oceanic Hydrozoa; a Description of the Calycophoridæ and Physophoridæ* observed during his voyage, was published by the Ray society with illustrative plates. He has since published papers on the glyptodon, and the osteology of that genus; and in papers on the mollusca, has shown that those animals have a common type or plan, similarly to the annulosa and vertebrata. Mr. Huxley contributed largely to the *English Cyclopædia;* and papers by him have appeared in the journals of the royal, the Linnæan, the geological, the zoological, and other learned societies. *Man's Place in Nature* appeared in 1863; *Lectures on Comparative Anatomy,* in 1864; *Lessons in Elementary Physiology,* in 1866; *An Introduction to the Classification of Animals,* in 1869; *Lay Sermons, Addresses, and Reviews,* in 1870; *Critiques and Addresses,* in 1873; *American Addresses* and *Physiography* in 1877; and a short work on *Hume* in 1879. Prof. Huxley was a member of the London school board till 1872. He is professor of natural history in the royal school of mines, and Hunterian professor of anatomy to the royal college of surgeons; an LL.D. of Edinburgh; and was in 1872 elected rector of Aberdeen university.

HUY, a strongly fortified t. of Belgium, in the province of Liege, is romantically situated amid lofty rocks on both banks of the Meuse, and in the immediate neighborhood of the finest scenery of that river, 17 m. s.w. of Liege. Its citadel, the works of which are partly excavated in the solid rock, commands the passage of the river. The church of Notre Dame, a graceful Gothic edifice, was begun in 1311. In the vicinity are iron-works and coal-mines, in the products of which the inhabitants carry on a lively trade by means of the Liege and Namur railway. The principal manufactures are paper, leather, zinc, beer, spirits, and an inferior kind of wine. Pop. '70, about 11,000.

Peter the hermit, on his return from the first crusade, founded here the former abbey of Neufmoustier (*Novum Monasterium*), and was himself interred within it. Huy has been frequently taken during the wars, of which this region has been the seat. It was last captured by Marlborough and Coehoorn in 1703.

HUYGENS VAN ZUYLICHEM, CHRISTIAN, one of the great philosophers of the 17th c., was b. at the Hague, April 14, 1629, and was the second son of Constantine Huygens, secretary and counselor to the princes of Orange. Huygens studied at Leyden and Breda. His first work, *Theoremata de Quadratura Hyperboles, Ellipsis, et Circuli, ex Dato Portionum Gravitatis Centro* (Leyden, 1651), is an example of that powerful geometrical talent which lay at the foundation of all his scientific achievements. Soon after this, he constructed the pendulum-clock, following out the idea first suggested by Galileo (q.v.). A complete description of Huygens's instrument is contained in his great work, *Horologium Oscillatorium, sive de Motu Pendulorum* (Hague, 1658).

This work contains expositions of many of the cases of constrained motion, especially those applicable to the construction of time-keepers. Huygens has also developed and given precision to the investigations of Galileo upon accelerated motion under the action of gravity; and there is no doubt that to the clearness of his demonstrations, his great successor, Newton, in preparing his magnificent development of the principle of accelerating force, was largely indebted. Newton was a student and admirer of his works, and assigns to him, along with sir C. Wren and Wallis, the distinguished epithet of *hujus ætatis geometrarum facile principes.*

By means of an improved telescope of his own construction, Huygens, in 1655, discovered the ring of Saturn and the fourth satellite of that planet. In 1659 he published an account of these discoveries in a work entitled *Systema Saturnium, sive de Causis Mirandorum Saturni Phenomenon, et Comite ejus Planetâ Novo.* In the end of this work is described an invention of great importance in astronomy—namely, the micrometer (q.v.), by which small angles between objects viewed by a telescope are accurately measured. In 1660 Huygens visited England, where he was admitted a member of the royal society. He discovered the laws of collision of elastic bodies

about the same time with Wallis and Wren, and also made a material improvement in the air-pump.

In 1666 Huygens received an invitation to settle in France, with the promise of a pension from Colbert, then all-powerful in that country. He repaired to Paris, where he remained till 1681, having been admitted to the membership of the royal academy of sciences; but alarmed at the danger which seemed impending over the Protestants, he returned to his own country. After his return he still continued his favorite pursuits till his death at the Hague, June 8, 1693.

The optical works of Huygens lastly claim our attention. They are chiefly remarkable for his maintaining a theory of light, which opposed as it was to the then more popular theory of Newton, is substantially the same with that which is now called the *undulatory theory*. By means of his theory, he explained the ordinary phenomena of reflection and refraction, and further succeeded in a satisfactory explanation of the phenomenon of double refraction, which Newton's theory failed to account for.

HUYGENS (VAN ZUYLICHEM), CHRISTIAN (*ante*). The discovery of the ring of Saturn was not made with the first telescope with which Huygens discovered the fourth (then the first) satellite. That instrument, although the most powerful then made, had a focal length of only 10 feet. The ring was discovered in 1659 with a telescope of 22 ft. focal length, which besides being much more powerful than the first, had a greatly improved construction of the eye glasses—essentially the same as those used at the present day, with the exception of the achromatic combination of lenses, a comparatively recent discovery. The discovery of the ring of Saturn was one of the master exploits of science. The appearance of two luminous bodies on either side of the planet at various times had been observed by Galileo, but his telescope did not enable him to make out anything more. The appearance of the two luminous points was found by Huygens to be caused by a position of the ring by which it reflected the sun's rays. From an examination of the subject he made calculations which foretold the disappearance of the ring from view in 1671. The discovery was published in 1659 in a volume which contained, among several other discoveries, an account of the bands upon the disks of Jupiter and Mars, and of the great nebula in Orion. His *Horologium Oscillatorium*, a part of which was published in 1658 at the Hague, was not completed till 1673, and published at Paris. This book contains 13 theorems on centrifugal force, which led to most important results in the science of mechanics, and in the same work he gives a method for finding the center of oscillation. Mersenne had proposed the problem of the center of oscillation in 1646, which was not solvable by any of the then known mathematical methods. It had attracted Huygens's attention at the time, but his youthful mind was unable to cope with the subject. However, when the last part of the *Horologium* appeared, in 1673, the problem was completely solved by a method which was the first solution of a dynamical problem in which connected material points are supposed to act on one another. Newton afterwards demonstrated these 13 theorems of Huygens in a manner of his own. Huygens's own demonstrations were found after his death among his papers. The first two theorems contain the assumption of the two first laws of motion, and in his treatise *De Motu Corporum ex Percussione* he assumed the third law of motion, which Newton afterwards expressed in the words "action and reaction are equal and opposite," an equivalent for saying that the impact of two bodies does not change the quantity of motion in them—one of the grand principles of the doctrine of conservation of forces. His works were edited by 'sGravesande in four volumes, entitled *Opera Varia*, 2 vols. 4to; in one volume, Leyden, 1724; and *Opera Reliqua*, 2 vols. 4to, Amsterdam, 1728.

HUYSUM, JAN VAN, a celebrated Dutch painter of flowers and fruits, was b. at Amsterdam in 1682, and acquired the rudiments of his art from his father, a landscape-painter of very considerable talent. Huysum surpassed all his predecessors in mellowness, purity, and delicacy of coloring; the exquisite disposition of his lights and shadows; and, above all, in his miraculous rendering of dew-drops and the motions of insects. He died at Amsterdam in 1749. Huysum's masterpieces are to be found in the galleries of Vienna, Munich, Dresden, and St. Petersburg.

HY'ACINTH, a name given to the brilliantly colored varieties of the gem called zircon, also to fine red cinnamon-stone (q.v.) or pyrope (q.v.); and sometimes to ferruginous quartz of a blood-red color, which, from its occurring abundantly in gypsum at Compostella, in Spain, is called *hyacinth of Compostella*.

HYACINTH, *Hyacinthus*, a genus of plants of the natural order *liliaceæ;* bulbous-rooted plants with corolla-like, bell-shaped, 6-cleft perianth, six stamens fixed in the tube of the perianth, and dry capsular fruit.—The *oriental hyacinth* (*H. orientalis*), one of the most favorite of florists' flowers, is a native of Asia Minor, Syria, and Persia. It is now naturalized in some parts of the s. of Europe. It has broad linear leaves, and a scape with a raceme of many flowers pointing in all directions. The flowers in cultivation exhibit great variety of color, chiefly blue, purple, and white. They are very beautiful and very fragrant. The fragrance is strongest about or after eleven o'clock at night. Among cultivated hyacinths are many with double flowers. The hyacinth has been cultivated from a remote period, but about the beginning of the 18th c., it attained almost the first place as a florists' flower. Great attention was bestowed on the produc-

tion of new varieties, and enormous prices were given for bulbs of some of them. A price equal to £200 sterling was sometimes paid for a single bulb. The principal seat of the cultivation of hyacinths was and still is at Haarlem. At present, however, more than £10 is seldom asked for the finest new variety of hyacinth, but although the trade is considered as now much depressed, the Haarlem gardeners still sell bulbs to the value of £2,000 or £3,000 yearly. Hyacinth bulbs, planted in pots, readily produce beautiful flowers; and flowers almost equally beautiful are obtained—for one year, however, only—by placing them in water in hyacinth *glasses*, in which they form a favorite ornament of apartments in winter and early spring. The cultivation of the hyacinth in the open ground is much more difficult. New varieties are raised from seed. Several other species of hyacinth are natives of the s. of Europe, Africa, etc.—The GRAPE-HYACINTH and GLOBE-HYACINTH, frequently cultivated as garden flowers, are now referred to the genus *muscari*.—A common British plant, growing in woods and copses, with beautiful blue flowers very like those of the oriental hyacinth, but all drooping to one side (*H. non-scriptus*, also known as *Scilla nutans*, *Endymion nutans*, and *Agraphis nutans*), is sometimes called the WILD HYACINTH, and sometimes the BLUE-BELL. The bulbs have been used for making starch.

HYACINTHE, PÈRE. See LOYSON, CHARLES.

HYACIN'THUS, in Greek mythology a boy of great beauty, an especial favorite of Apollo, but also beloved by Zephyrus. While playing at discus with Apollo, he was struck and killed by one of the missiles thrown in jealous rage by Zephyrus. Apollo changed him into the flower known by the name hyacinth, on whose petals the Greeks fancied they saw inscribed the name of the unfortunate boy.

HYA-HYA. See COW TREE.

HYALEA, a genus of mollusks belonging to the class *pteropoda*. They are noted for the beautiful transparent glassiness of the texture of their pyramidal shells. See PTEROPODA.

HYANNIS, a seaport village in Barnstable co., Mass., on a branch of the cape Cod railroad; pop. est. 3,300. There are a number of manufactories in the village, a high school, and five churches. It is also a place of summer resort, and is connected with Nantucket by steamboat.

HYBERNA'TION. See HIBERNATION.

HY'BODUS (Gr. *hump-tooth*), a genus of fossil fish, whose teeth and osseous fin-rays are found in all the secondary rocks from the trias to the chalk inclusive. The genus, with the small family of hybodonts to which it belongs, occupy a place between the cestracionts, with their pavement of flat crushing teeth, and the sharks with their sharp-pointed cutting teeth. The teeth of the hybodonts are conical, but broad and blunt; from the body of the tooth rises a large central cone, and several small lateral ones, decreasing in size as they recede from the principal cone. The enamel is strongly marked by longitudinal grooves and folds. The osseous rays of the dorsal fins are the only other preserved portions of these fossils. Like the Port Jackson shark, the hybodus had each of the two dorsal fins furnished with a large and strong spine, one-third of whose length was buried in the flesh. Nearly fifty species of this genus have been described.

HY'BRID (Gr. *hybrid*, from *hybris*, extravagance, licentiousness) is the term applied by naturalists to the offspring of different but generally nearly allied species of animals and plants, and must be distinguished from the word *mongrel*, which is applied to the offspring of different varieties of the same species.

M. Broca, whose memoir on hybridity of animals is the most complete that has yet appeared, remarks that this condition may be (1) natural, (2) excited (*provoquée*), or (3) artificial. The first variety is such as occurs spontaneously amongst animals in their wild state; the second includes those cases in which domesticated animals, which would not naturally cross with one another, do so under the influence of man, and in opposition to their natural instincts; while the third variety is due to the artificial admixture of the male and female generative elements, and as far as is yet known occurs only in fishes, and in the vegetable kingdom. The second variety is by far the most common and the most important.

When the male of the species A can impregnate the female of the species B, it may happen that the process can be inverted, and that the male B can impregnate the female A. In other cases, however, while the male A can readily impregnate the female B, the male B cannot impregnate the female A. In the first case, the hybridity is termed *bilateral;* in the second, *unilateral*. The former is rare, and even when it does occur, the cross in one direction is more common and more productive than in the other. Thus, the ordinary mule, the offspring of the male ass and the mare, is much more readily obtained, and, physiologically, is less imperfect than the corresponding animal, the hinny, which occasionally results from the union of the stallion and female ass. See MULE, HINNY. Our domestic sheep and goats afford an example of the latter (unilateral) kind of hybridity. The union of the he-goat and the ewe is frequently productive, while the union of the ram with the she-goat is always unproductive.

In the present state of our knowledge, it is impossible to predicate in what cases

the crossing of different species will be productive, and in what cases it will be barren. While some closely allied species do not admit of a cross, other species, far more removed from one another, not only yield hybrids, but even fruitful hybrids. There is, however, a limit, beyond which the chance of offspring becomes reduced to zero, and, according to Broca: "If the crossing of animals of different genera is now an incontestable fact, there is no authentic evidence that offspring has resulted from the crossing of animals of different orders."

Cases have been referred to, as showing that animals of different orders may cross, but none of them are satisfactorily established. The strongest apparent case of hybridity between different orders is that of the *jumarts*, which were said to result from the union of the bull and the mare, or of the stallion and the cow. These jumarts were believed in from the time of Columella to that of Buffon, who fully investigated the subject, and found that they were merely hinnies—the offspring of the stallion and the she-ass. Among mammals, hybrids have been obtained between the different species of the genus *equus*. So far as experiments go, the horse, the ass, the zebra, the quagga, etc., breed freely *inter se*, but the degrees of fertility among their offspring have not been fully determined. The dog has been made to breed with the wolf and the fox, the lion with the tiger, the he-goat with the female sheep, the ram with the female roe-deer (*cervus capreolus*), and the hare with the rabbit. (See Professor Owen's article, "Hybrid," in Brande's *Dictionary of Science, Literature, and Art.*) A case was recorded some time ago in *The Field* newspaper, in which a prolific union took place between a mastiff dog and a lioness that had been brought up together.

Among birds, hybridity is not uncommon. The swan will breed with the goose, the grouse with the blackcock, the pheasant with the common fowl, the goldfinch with the canary, etc. Among reptiles, hybrid offspring has been observed between the toad and the frog. Among fishes, hybrids have been obtained by artificial impregnation between different species of the genus *cyprinus*.

Many hybrids have no propagative power, while in others it is so far limited as to admit only of reversion to the original specific form. When a hybrid possesses generative power, it breeds more readily with an individual of one of its parent stocks than with another hybrid like itself. The most remarkable example on record of generative power in hybrids is afforded by the experiments of M. Roux of Angoulême, who finds that he can cross hares and rabbits to any extent, and who has thus, by breeding *leporides*, established a new and lucrative department in agriculture. For a full account of these experiments, which are well deserving of a trial in this country, the reader may consult Brown-Sequard's *Journal de la Physiologie*, vol. ii. pp. 374–83. These experiments have inflicted a severe blow on the popular doctrine of the permanence of species.

Experiments on the hybridization of plants have been very far from confirming the hybrid origin of forms apparently intermediate between other species, and which were once regarded as probably hybrids produced in a state of nature. The interference of man is usually necessary to effect an intermixture, and in many cases in which it has been found possible, it is by no means of easy accomplishment. The predilection for pollen of the same kind appears to be very strong; and if pollen, both of the same and of another kind, is applied to the stigma of a flower, the result is the same as if its own pollen had been there alone. The hybridizer, therefore, must cut away the stamens of the flower of which the pistil is to be impregnated, and carefully prevent all access of pollen other than that which he brings to it. Even with these precautions, it is found impossible to produce hybrids between some plants of the same family, and not very dissimilar.

Hybrid plants are said to partake generally of the characters of the male more than of the female parent. It is more certain that valuable results are often obtained as to size and abundance of fruit, brilliancy of flowers, hardiness, and other qualities. The question of the continued fertility of true hybrids is one having most important relations to the great questions concerning species. Some assert that neither among animals nor among plants are hybrids fertile for more than one or two generations, if kept by themselves; although they are readily fertile with either of the parent species, to which they become again assimilated. But this opinion is controverted, and the question must, of course, be decided by observation of facts, in judging of which, however, questions of no little difficulty must often arise as to what are and what are not different species.

The subject of the hybridization of plants was first investigated, and with great care and very numerous experiments, by Kölreuter, in the end of the 18th c. and has been more recently studied with much attention by Dean Herbert of Manchester, Van Mons, and particularly Gaertner.

HYDASPES. See JHELUM.

HYDATID (from the Greek *hydatis*, a watery vesicle), a term indefinitely applied to several distinct objects of a vesicular or cyst-like character, which are found in the bodies of men and certain mammals. True hydatids were formerly regarded as cystic entozoa (q.v.), such as cysticercus, cœnurus, and echinococcus, but all these animal forms are now discovered to be larval stages of tænia or tape-worm (q.v.). These hydatids may occur in almost any part of the body, and they have been observed in

man, the ape, the ox, the sheep, the horse, the camel, the pig, the kangaroo, and some other vegetable feeders, but they apparently do not occur in carnivorous animals or in the rodents. They are generally inclosed in an external sac, which is attached to the tissue of the organ in which it is situated, and which is frequently common to many hydatids, each of which has a distinct envelope. The fluid in the interior of the hydatid itself is almost always colorless and limpid, but the fluid in the common cyst in which the hydatids float is often of a yellow color. The *cœnurus cerebralis* is found in the brain of various ruminants, and gives rise to the disease in sheep known as "the staggers." When the hydatid occurs in the fourth ventricle, the animal, instead of turning round and round in one direction, springs in the air, and this variety of the affection is hence distinguished by German veterinarians as *das Springen*. Whenever any of the above forms of hydatids are swallowed by man or the lower animals, they may proceed, under favorable circumstances, to be developed into the higher stages of tape-worm. Two species of echinococcus are usually noticed, namely, the *E. hominis*, which has been occasionally met with in the brain and abdomen of man, and the *E. veterinorum*, which is of common occurrence in various parts of the body of the pig, and several other mammals, but it is by no means certain that they are really distinct. These echinococci do not become developed into tape-worms unless they reach the intestinal canal of some animal, by being taken as food; and in ordinary cases of hydatids, consisting of echinococci, the cysts and their contents undergo a kind of degeneration, becoming in some cases converted into fatty or calcareous matter, while in other cases the contents become granular, the peculiar hooklets (which will be described in the article TAPE-WORM) which occur in them, and which remain unaltered for a long time, revealing their true origin.

The so-called acephalocyst, or common globular hydatid, which sometimes attains the size of a child's head, is probably a degenerated or abnormally developed echinococcus.

Hydatids sometimes occasion so little inconvenience, that persons, in whom they are discovered after death, have not suspected any disease in the organ in which they are found. On other occasions, they grow rapidly, and cause so much irritation that suppuration is excited in or around the common sac, which may either burst externally, or into a mucous canal or a serous cavity. In the first or second case, the hydatids will be discharged, and recovery may take place; in the third case, fatal inflammation will ensue. Little can be done for the treatment of this affection, except that occasionally, if the cyst is near the surface, it may carefully be punctured. The means of preventing the affection will be noticed in the article TAPE-WORM.

False hydatids are simple serous cyst, either occurring alone or in clusters, whose mode of origin is not distinctly understood. Structures of this kind, on a small scale, are common in the choroid plexus of the brain, while on a large scale they are found containing the fluid in ovarian dropsy. These false hydatids are also of a comparatively common occurrence in the uterus, which they may distend to such a size as to simulate pregnancy.

HYDE, an important manufacturing town of England, in Cheshire, is situated 7 m. e.s.e. of Manchester, and about the same distance s.e. of Oldham. Until a comparatively recent period, it was a mere village; but since the extension of the cotton-trade, on which it mainly depends, it has rapidly increased in size. Its pop. '71 was 14,223. Besides the numerous cotton-factories, iron, water, and print works are carried on. Coal abounds in the neighborhood. The district in which Hyde is situated is densely peopled, and is furnished with abundant means of communication, by railway and canal, with all the important towns in the vicinity.

HYDE, a co. in Dakotah, on the Missouri river, as yet unorganized. Part of it is an Indian reservation.

HYDE, a co. in e. North Carolina, on Pamlico sound; 600 sq.m.; pop. '70, 6,445—2,378 colored. The surface is level, and the soil sandy. Rice, corn, and pork are the chief products. Co. seat, Swan Quarter.

HYDE, ANNE, 1637–71; daughter of the earl of Clarendon, married clandestinely to the duke of York, over whom she had great influence, even after he became James II. Two of her daughters (Anne and Mary) were queens of England.

HYDE, EDWARD. See CLARENDON, EARL OF.

HYDE, THOMAS, 1636–1703; b. England; a celebrated oriental scholar, educated at Cambridge, and an assistant to Walton in an edition of the *Polyglot Bible*. Besides correcting the Arabic, Syriac, and Persian texts, he transcribed in Persian characters the Persian translation of the Pentateuch that had been printed in Hebrew shortly before at Constantinople, and appended a Latin version of his own. The success with which he accomplished these difficult tasks met the acknowledgment of the most learned men of the age. In 1658 Hyde entered Queen's college, Oxford, to which he was shortly after made Hebrew reader. In the following year, after graduating as M.A., he was chosen underkeeper, and finally librarian-in-chief of the Bodleian library. In 1660 he was made a canon of Salisbury; in 1678 archdeacon of Gloucester. The death of Pococke in 1691 opened up to him the Laudian professorship of Arabic; and soon after,

on the deprivation of Altham, he became regius professor of Hebrew and canon of Christ church. Worn out by his unremitting labors, he resigned his librarianship in 1701, and died two years later. The range of Hyde's erudition in oriental matters was vast. There was hardly an eastern tongue to be learned with which he was not familiar. He even knew Chinese—a language which very few Europeans of that day could boast of knowing. He learned it from Chin-fo-coung, a learned young Chinese brought to England by the Jesuits. His mastery of the more accessible languages of the east, such as Turkish, Arabic, Persian, Hebrew, and Armenian, is proved by his numerous and still valuable works.

HYDE PARK, a noble inclosure of nearly 400 acres, extending from the western extremity of London to Kensington gardens, which derives its name from having been the manor of the Hyde belonging to the abbey of Westminster. It became the property of the crown on the dissolution of the monasteries, in the reign of Henry VIII. A canal or sheet of water, called the Serpentine, although in the form of a parallelogram, was made in Hyde park, between 1730 and 1733, by order of queen Caroline. At the eastern end of it is an artificial waterfall, constructed in 1817. On the s. side are the barracks of the life-guards. It was in Hyde park that the great international exhibition of 1851 was held, in a crystal palace specially erected for the occasion. We do not clearly learn at what time the public began to have free admission to Hyde park. But Ben Jonson speaks of the show of coaches which it presented in his time; and we know that it was constantly resorted to on the morning of May-day for the sports comprehended under the term Maying. Till the middle of the 17th c., there was a part of it which contained deer. About that time it began to be a place for races and military reviews. It was also resorted to for duels. After the restoration it appears to have become the favorite promenade, which it has ever since continued to be. It has, however, undergone many changes of boundary and division; a large part of Kensington gardens has been taken from it, also an angle at the s.e. corner on which Apsley house now stands.

HYDE PARK, a village in Norfolk co., Mass., on the Boston and Providence and the New York and New England railroad, 7 m. from Boston; pop. '80, 7,090. It is a place of residence for Boston business men.

HYDERABAD', more properly HAIDARABAD (from *Haidar*, lion; and *bad*, town), the capital of the nizam's dominions (q.v.), stands on the right bank of the Mussi, in lat. 17° 22′ n., and long. 78° 32′ e., at an elevation of 1800 ft. above the sea, and contains, with suburbs, 200,000 inhabitants. On the opposite side of the river is the British residency, the stream being here bridged by nine spacious arches of squared granite. Besides these erections and the palace of the native sovereigns, we may mention the principal mosque which has been fashioned after the model of the Kaaba at Mecca; while at the meeting of the four principal streets of the city rises another remarkable edifice, with four minarets resting on four connected arches, on which run the four converging thoroughfares. The neighborhood abounds with huge tanks. One of them, close to the British cantonment of Secunderabad, measures 3 m. by 2; and another, still larger, is said to be 20 m. round.

HYDERABAD, the chief city of Scinde, stands 4 m. to the e. of the left bank of the Indus, in lat. 25° 22′ n., and long. 68° 28′ east. Pop. '72, 41,152. The place is famous for the manufacture of arms of various kinds, such as matchlocks, swords, spears, and shields. As against a native force it is tolerably strong, occupying a somewhat steep height, and having a rampart flanked by round towers.

HYDERABAD', a large district in s. India in the Deccan, intersected by many rivers of which Godavery is the chief; 95,337 sq.m.; pop. 11,000,000. It is a high tableland, having a climate unusually cool for its latitude. Cotton and wheat are the chief agricultural products. The manufactures are silk, carpets, and brocades. Cotton and timber are exported. The peninsular railway crosses the s. and e. portions of the district. About 90 per cent of the people are Hindus, though the government is Mohammedan.

HYDER ALI, ruler of Mysore, and one of the greatest Mohammedan princes of India, was born in 1728. His father, who was a gen. of the rajah of Mysore, afterwards obtained Bangalore in fief, and both of these honors descended to his son. Hyder Ali, in 1759, dispossessed his master, allowing him, however, to retain his title, while he himself took that of *daïva*, or regent. He then conquered Calicut, Bednor, Onor, Cananor, and other neighboring states; and in 1766 his dominions included more than 84,000 sq. miles. He waged two wars against the British, in the first of which he was completely successful, and dictated terms of peace under the walls of Madras, but died before the termination of the second, in which he was aided by the French. He also joined in a native confederacy for the expulsion of the British from India. He, besides, withheld the customary tribute from the Mahrattas (q.v.), and waged a successful war against them. In his wars he displayed great resolution and perseverance. He died in 1782. Hyder Ali was remarkable among Asiatic princes for the mildness of his character and government, and was much beloved by his people. He promoted agriculture,

commerce, and the arts, and protected all religions, requiring only submission to his laws. His son and successor was Tippoo Sahib (q.v.).

HYDNO'RA, a genus of plants of the natural order *rhizanthaceæ*. *H. Africana* is a native of South Africa, where it is called *jackal's kost*. It is a parasite chiefly on the roots of large succulent spurges, and is a plant of most extraordinary appearance and structure, resembling a fungus rather than a phanerogamous plant. Its flowers and fruit are entirely concealed in its interior. It has a smell like that of a fungus, or of decaying roast-beef. The South African savages roast and eat it.

HYDNUM, a genus of fungi (*hymenomycetes*), having the under side of the *pileus* covered with soft spines which bears the spores. The species are pretty numerous, some of them British; among which is *H. repandum*, more common in some parts of the continent of Europe, and much used as an esculent in France, Italy, and Germany. It grows on the ground, chiefly in pine and oak woods, either solitary, or in clusters or rings.

HY'DRA, THE, or fresh-water polype, is the type of the class HYDROZOA, which, with the ANTHOZOA, form the sub-kingdom *cœlenterata* of recent zoologists. See ZOOPHYTE.

The hydra possesses a gelatinous, sub-cylindrical body, which, from its contractility, undergoes various alterations of form. One end expands into a disk or foot, which adheres to a leaf, twigs, etc.; while a mouth, surrounded by a circlet of tentacles, varying from five to twelve or more in number, is situated at the opposite end. These tentacles are exceedingly contractile, at one moment thrown out as long delicate threads, at the next, drawn up into minute wart-like knobs. Numerous thread-cells project from their surface, the larger ones possessing a sheath and three recurved darts or barbs, and terminating in a long and extremely slender filament. The mouth leads into a capacious cavity, excavated throughout the whole length of the animal, which, exclusive of its tentacles, seldom exceeds three-fourths of an inch. On minutely examining the hydra, or any member of the class hydrozoa, the body is found to be composed of two membranes, an ectoderm and an endoderm, the former constituting the outer layer of the animal, and having one side always in contact with the water, while the other side is in close contact with the endoderm, whose free surface forms the lining of the great internal cavity. The food of the hydra consists of such minute living organisms as come within the reach of its tentacles, and by these apparently fragile threads, which the animal projects like a lasso, crustaceans, worms, etc., are seized, which would be deemed at first sight superior to their captor in strength and activity. The tentacles appear, however, to possess, through the action of the thread-cells, a powerful benumbing or paralyzing influence, for it has been observed that soft-bodied animals which have succeeded in escaping from the grasp of the hydra frequently die very shortly. The prey, when mastered, but often when still alive, is thrust into the internal cavity, where the nutritive parts are absorbed by the hydra, while the indigestible portions are expelled through the mouth.

Although the hydra is usually found adhering by its circular foot or disk to submerged leaves, twigs, etc., it is not permanently fixed. It often moves on surfaces under water somewhat after the manner of a leech, both ends taking a part in the movement, and occasionally the disk is protruded above the water, and thus acts as a float.

Sometimes, especially in the autumn, true reproductive organs may be observed, both male and female organs being usually situated on the same animal. Propagation by gemmation is, however, the most common mode of increase. Minute tubercles appear on the body of the parent animal, which, as they increase in size, gradually resemble it; becoming perforated at their free extremity, and tentacles gradually being formed. The pedical by which they originate by degrees becomes thinner, and finally gives way, leaving the young hydra perfectly independent. One of the most remarkable points in the history of this animal is its power of being multiplied by mechanical division. If a hydra be cut into two, or even more pieces, every one will, in time, assume the form and functions of the original animal.

Several species of hydra such as *H. viridis*, *H. vulgaris*, *H. fusca*, etc., have been described, which differ in size, color, etc. When living hydræ are removed from the water, they appear like minute specks of jelly, which quickly recover their true form on being restored to their proper element. The great authority on these singular animals is Trembley, whose *Mémoires pour servir à l'histoire d'un Genre de Polypes d'eau douce* was published in 1744.

HYDRA, a fabulous monster of the ancient world, said to have inhabited the marshes of Lernæa, in Argolis, not far from the sea-coast. Accounts vary both as to its origin and appearance. Some make it the issue of Styx and the Titan Pallas, and others, of Echidna and Typhon. It is represented as having several heads, which immediately grew up again as often as they were cut off. The number generally ranged from seven to nine, though Simonides gives it fifty, and certain historians a hundred, and even more. Its mouths, which were as numerous as its heads, discharged a subtle and deadly venom. The destruction of this reptile was one of the twelve labors of Hercules (q.v.).

HYDRA, an island of Greece, is situated off the eastern shore of the Peloponnesus (now the Morea), about 5 m. distant from the coast of the department of Argolis and Corinth. It is about 13 m. long and 3 m. broad, and has an area of 38 sq. miles. The shores are rocky and steep, and the interior, rising to about 1800 ft. in height, is destitute of vegetation and of water. On the n.w. coast is the town and seaport of Hydra, the white, flat-roofed houses of which, ascending from the harbor, climb up the side of a hill. The streets, owing to the irregularity of the site, are steep and uneven, but remarkably clean. This town, the only one in the island, is one of the most beautiful in the whole of Greece. Pop. '71, 11,684, who are chiefly employed in cotton and silk weaving, in tanning, and in commerce.

The island of Hydra was uninhabited in ancient times. The nucleus of the town was formed by a few fishermen and peasants, who, suffering from the oppression of the Turks, crossed over from the neighboring mainland, and were afterwards followed by crowds from Albania, Argolis, and Attica, in the 15th and 16th centuries. In the Grecian war of independence the Hydriotes took a most active part; and none were more liberal in their contributions to the patriotic cause. In 1825 the population was estimated at 40,000, and about that time the islanders were considered the richest in the archipelago. They possessed exclusively the carrying-trade of the Black sea and the Mediterranean, and traded to England, the Baltic, and even America. Since the revolution, however, more accessible ports have risen to be the centers of Greek commerce, and Hydra has considerably declined.

HYDRA'CIDS, or HYDROGEN ACIDS, a name given to acids in which the acidifying principle was supposed to be hydrogen. See ACIDS. The division of acids into *oxyacids* and *hydracids* belongs rather to a past than to the present state of chemistry.

HY'DRAGOGUES are those active purgatives which produce a great flux from the intestinal membrane, and which consequently give rise to very watery stools. They are of extreme use in some of the varieties of dropsy, being the most effectual means of diminishing the liquid poured into the cellular tissue and serous cavities of the body.

Jalap (especially when combined with bitartrate of potash) and elaterium, a medicine which, from its extreme power, must be given in very small doses (one-eighth to one-third of a grain), and with great caution are perhaps the best examples of this class of purgatives.

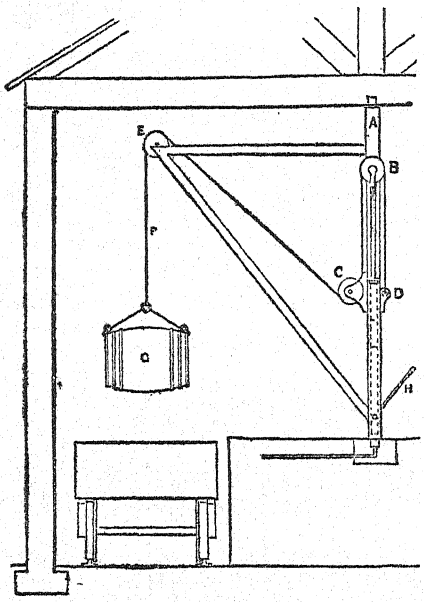
HYDRAN'GEA, a genus of plants of the natural order *hydrangeaceæ*, which many botanists make a suborder of *saxifrageæ*, distinguished by having 4 to 6 petals, 8 to 12 or many stamens, a more or less inferior ovary, and 2 to 5 styles. *Hydrangeaceæ* are shrubs with opposite, or sometimes whorled leaves, destitute of stipules. In the genus hydrangea the flowers are in cymes, the exterior flowers sterile and dilated. Few species are known, and they are chiefly natives of the southern parts of North America, and of China and Japan. The species popularly known as the HYDRANGEA (*H. hortensia*), is a native of China and Japan, and has long been in cultivation there as an ornamental plant. It was introduced into Britain by sir Joseph Banks in 1788, and speedily became very popular, being readily propagated by layers and cuttings, so as to be not only a favorite green-house plant, but a frequent ornament of cottage windows. In the s. of England, it endures the open air. It seems almost impossible to water it too freely; a large plant has been known to receive with advantage one hundred gallons of water daily; and in favorable circumstances, it becomes a magnificent shrub. A plant in Devonshire has had 1,000 large cymes of flowers expanded at once. The flowers, generally pink, are sometimes blue; the blue color is owing to peculiarities of soil. Peat and iron ore are said to be productive of blue flowers in the hydrangea.—*H. Japonica*, introduced into Europe from Japan by Siebold, is remarkable for its very large cymes of flowers.—*H. nivea* and *H. quercifolia*, American species, are not unfrequently to be seen in flower-gardens in North America.

HYDRAS'TIS, or WARNERIA, a genus of plants of the natural order *ranunculaceæ*, allied to *anemone*, but having flowers destitute of petals, and succulent or *baccate* fruit, collected into a head. The only known species, *H. canadensis*, a perennial herbaceous plant, with tuberous roots, and head of fruit resembling a raspberry, is common in watery places in Canada, and among the Alleghanies, as far s. as Carolina. Its root is used for dyeing yellow, and also in medicine as a tonic. YELLOW ROOT and ORANGE ROOT are its American names.

HY'DRATES are substances in which a definite quantity of water is chemically combined with a definite quantity of some other constituent. Although water is a perfectly indifferent substance, possessing neither acid nor basic properties, yet it enters into combination both with acids and with bases, and thus forms the bodies termed hydrates. Thus, when an acid has once been allowed to combine with water, the entire separation of the water can usually only be effected by the presence of some strong base, which displaces the water. If, for example, we distill diluted sulphuric acid, water is expelled up to a certain point, when both acid and water are distilled together. The liquid now contains one equivalent of water, and one of acid (HO,SO_3), and is termed hydrated sulphuric acid, and this equivalent of water can only be displaced by an

equivalent of potash, or some other base. Hydrate of baryta (BaO,HO), hydrate of lime or slaked lime (CaO,HO), hydrate of sesquioxide of iron (Fe_2O_3,3HO), and hydrate of oxide of copper (CuO,HO), are similar cases, except that here the water is displaced by an acid instead of a base. The above are examples of hydrates of acids and bases or oxides. Gypsum (CaO,SO_3,2HO) is an example of a hydrate of a salt.

HYDRAULIC CRANES have come into very extensive use within the past few years. Wherever a large number of cranes have to be worked near each other, water-pressure is by far the most manageable, economical, and convenient mode of working them. Sir W. Armstrong & Co., of Newcastle, have taken the lead in introducing this kind of machinery. They have fitted up a great many railway goods stations with complete systems of hydraulic cranes.



The figure represents one of the simplest forms of hydraulic cranes, such as are in use for loading goods in a railway station. It is made entirely of iron, and consists of two upright cheeks, A, between which there is fixed a hydraulic ram (similar to that used in the hydraulic press), occupying the lower half of the upright frame A. The upper end of this ram carries a pulley B. A similar pulley is fixed to the upright frame at C. A chain is secured to a bracket, D, on the upright frame. This chain passes up over the pulley B, down and under the pulley C, and then over the pulley E, on the end of the jib of the crane. It is obvious that the rising and falling of the ram will cause the chain, F, to ascend and descend with its load G.

The ram is forced to ascend by the admission of water under great pressure by the handle H, which serves also to allow the water to flow out after it has done its work, and the ram descends by its own weight, allowing the chain, F, to run down with or without a load on it.

The pressure usually employed in working hydraulic cranes is greatly in excess of the pressure admissible in the case of steam. Six or seven hundred pounds to the sq. in. is usually employed as the working-pressure. It is got up to this great pressure by means of an arrangement called an accumulator, which consists of a large hydraulic ram of 16 or 18 in. in diameter, carrying a wrought-iron cylinder. This cylinder is filled with stones or gravel to the weight of 60 or 70 tons. A powerful horizontal steam-engine forces water into a cylinder and slowly raises the ram with its enormous load. Pipes lead away from the cylinder to the cranes in the different parts of the station, and are thus supplied with water under the great pressure caused by the load forcing the ram into the cylinder. The load is constantly rising and falling a little as the cranes draw their supplies from the cylinder. If the cranes were supplied direct from the force-pumps of the steam-engine, without the intervention of this accumulator, their action would be jerky and unsteady. The accumulator acts as a reservoir of power, and when it happens that a great number of cranes are drawing off water at the same moment, and in excess of what the engine force-pumps can supply, the ram descends, keeping up the while the full 700 lbs. pressure; and then, when the cranes are demanding less abundant supplies, the engine overtakes its work, and sends the ram up again. When it arrives at the top it touches a lever communicating with the throttle-valve of the engine, and thus slows or stops the engine when the accumulator has mounted to its maximum height. The moment it begins to descend, the lever is relieved, the throttle-valve opens, and the engine goes on again with such speed as the work demands.

It is easily seen that when the pulley rises any given distance, the weight will, at the same time, rise *double* that distance, because it raises a double length of chain; and, in the same way, by passing the chain twice, thrice, or any greater number of times over the pulleys, the weight can be made to travel any number of times further than the ram. It is, in fact, the reverse action of a block and tackle. If the block is made to move, the *fall* will move further than the block in proportion to the number of times the rope passes over the sheaves. This kind of arrangement is adopted when it is desired to lift anything to a considerable height, such as grain to upper floors of a warehouse. There is, of course, a diminution in the weight the machine can hoist, in proportion to the excess of travel of the load to that of the ram.

The hydraulic lifts, or ascending rooms, now in use in many large hotels, are con-

structed on the same plan as the accumulator. A cylinder is sunk 60 or 70 ft. into the ground, thus admitting a ram of nearly equal length to rise out of it, on a sufficient pressure of water being forced into it by a steam-engine. The ascending room takes the place of the loaded cylinder. Balance weights are attached to the ascending room, to steady its movements and to guard against any failure in the mechanism. A rope passing from bottom to top of the channel, through which the ascending room rises, affords to the person in the room the means of regulating its movements.

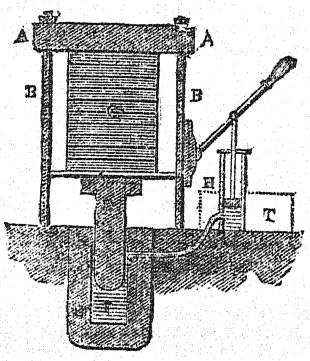
HYDRAULIC ENGINES are sometimes used where water under high-pressure is obtainable. They do not differ in any essential particular from a steam-engine. As the pressure under which they work is from five to ten times greater than that of a steam-engine, they are much smaller. One form of hydraulic engine is described under the head of WATER-POWER. Another common form is that of three small cylinders in which three plungers work. The water is admitted into the cylinders by means of valves, and forces the plungers outwards. These plungers are connected with a three-throw crank; and when they have completed their outward travel, or working-stroke, the water is allowed to escape from the cylinder; the plunger then slides inwards, to be again forced outwards by a fresh rush of water admitted at the proper instant into the cylinder by the action of the valve.

HYDRAULIC FORGING, forging with the hydraulic-press instead of the hammer and anvil. The process is analogous to that of rolling. The advantages claimed for the process are that it is, in many operations, more expeditious than the ordinary modes, and also that it produces a better structural condition of the particles of the material, the force being less superficial than the sudden impact of a hammer, and moving the particles of matter near the center to a greater extent, thus rendering the forged bar more homogeneous. Every forger and observant person has noticed that in the ordinary mode of forging a bar of iron there is, when the bar is thick enough, a protrusion of material at the edges, leaving a groove in the middle of the thickness, because of the superficial parts of the bar having received the greatest spread. Rolling or forging by pressure avoids this. Forging by hydraulic pressure is practiced in Europe. At Vienna there are several presses in operation, one with a piston 24 in. in diameter, transmitting a pressure of 2,400,000 lbs.

HYDRAULIC JACK, a machine which often takes the place of the jack-screw for raising heavy weights. It is simply a form of hydraulic press, which may be placed beneath a house, or ship, or any great weight which it is desired to raise—generally consisting of a stout frame furnished with upright grooves, in which a follower may be forced upwards by a hydraulic cylinder. By proper appliances the power may be rendered almost immeasurably great. See HYDRAULIC PRESS and JACK-SCREW.

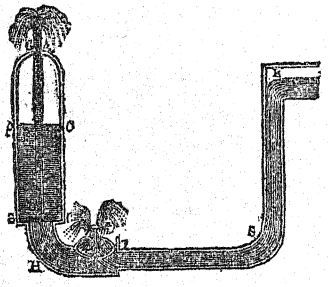
HYDRAULIC LIMES. See CEMENTS.

HYDRAULIC PRESS, called also Bramah's press, from the name of its inventor, depends on the principle, that a pressure exerted on any part of the surface of a liquid is transmitted undiminished to all parts of the mass, and in all directions. See HYDROSTATICS. The annexed figure represents the essential parts of the machine, the details of construction being omitted. F is the cavity of a strong metal cylinder E, into which the piston, D, passes water-tight through the top. A tube, G, leads from the cylinder to a force-pump H; and by means of this water is driven from the tank T into the cavity F, so as to force the piston, D, upwards. The piston supports a table on which are placed the bales, books, or other articles to be pressed; and the rising of the table presses them against the entablature AA, which is fastened to the pillars B B. The power of the press is readily calculated. Suppose that the pump has only one-thousandth of the area of D, and that, by means of its lever-handle, the piston of the pump is pressed down with a force of 500 lbs., the piston of the barrel will rise with a force of one thousand times 500 lbs., or more than 200 tons. The rise, however, will be slow in proportion to the power. The enormous multiplying power given by this machine has been employed for a great variety of useful purposes, such as compressing bales of cotton, paper, etc., expressing oils, bending iron plates and bars, and raising weights. This was the means employed for launching the *Great Eastern* at Millwall, and for raising to their position the tubes of the Britannia bridge.



HYDRAULIC RAM, a simple and conveniently applied mechanism, by which the momentum or weight of falling water can be made available for raising a portion of itself to a considerable height. In the annexed figure, which represents a section of Montgolfier's hydraulic ram, R is the reservoir from which the water falls, RS the height of the fall, and ST the horizontal tube which conducts the water to the engine ABHTC.

E and D are two valves, the former of which closes its cavity by ascending, the latter by descending; and FG is a pipe reaching within a very little of the bottom CB. The valves are such that the water at its normal pressure cannot support their weight; the valve E is prevented from falling below a certain point by a knob above *mn*. When the water is allowed to descend from the reservoir, after filling the tube BHS, it rushes out at the aperture *mn*, till its velocity in descending RST becomes so great as to force up the valve E, and close the means of escape. The water being thus suddenly checked, and unable to find a passage at *mn*, will produce a great action on every part of the containing vessels, and by its momentum raise the valve D. A portion of water being admitted into the vessel ABC, the impulse of the column of fluid is expended, the valves D and E fall; the opening at D being thus closed, and that at *mn* opened. The water now rushes out at *mn* as before, till its motion is again stopped by its carrying up the valve E, when the operation is repeated, the fluid impulse opening the valve at D, through which a portion of the water passes into ABC. The valves at E and D thus alternately closing and opening, and water at every opening of D making its way into ABC, the air therein is condensed, for it has no communication with the atmosphere after the water is higher than the bottom of the pipe FG. This condensed air, then, exercises great force on the surface, *op*, of the water, and raises it in the tube, FG, to a height proportioned to the elasticity of the imprisoned air. The principles of the hydraulic ram are susceptible of a very extensive application. In well-constructed rams, the mechanical effect obtained has been found to be about two-thirds of the energy in the falling water. For raising comparatively small quantities of water, such as are necessary for the supply of single houses, farm-yards, etc.—where water at the lower level is plentiful and cheap—the hydraulic ram is a most useful piece of mechanism. Its details have been greatly improved since the time of Montgolfier.



HYDRAULICS. See HYDRODYNAMICS and HYDROSTATICS, *ante*.

HY'DRIDÆ, a family of serpents, sometimes so defined as to include numerous fresh-water snakes which are not venomous, and sometimes limited to venomous sea-serpents, inhabiting the Indian, Chinese, and tropical Australian seas. These sea-serpents, forming the genus *hydrophis* (or *hydrus*), and other genera recently separated from it, have the tail compressed and the belly keeled, so that they have the power of swimming like eels; they have small heads and small eyes; they are remarkable for the large size of their nasal shields; they are generally of a yellowish-green color, varied with blackish rings or lozenge-shaped spots. Their lungs are often prolonged into a reservoir of air as far as the commencement of the tail. They are often from 2 to 5 ft. long. They are frequently seen asleep on the surface of the sea, and are easily caught in this condition, in which, apparently, they often fall a prey to sharks. They are supposed to live on small fishes and crustaceans. They are sometimes found coiled up among seaweed on the shore, and are much dreaded by fishermen. In some places they are very numerous. One species, at least, is esteemed good food by the Tahitians. More than 50 species are known.

HY'DRIDES. This term is applied both to combinations of hydrogen with metals, and to similar combinations with organic or compound radicals. Hydrogen forms hydrides with at least four metals—viz., arsenic, antimony, copper, and potassium. The first two of these are the well-known gases, arseniuretted hydrogen (AsH_3) and antimoniuretted hydrogen (SbH_3). The hydride of methyl or marsh-gas (C_2H_3,H), and the hydride of ethyl (C_4H_5,H), are examples of the second variety of hydrides.

HYDROCAR'BONS. See CARBOHYDROGENS.

HY'DROCELE (Gr. *hydor*, water, and *kēlē*, a swelling) is the medical term for a dropsy of the tunica vaginalis, a serous membrane or sac investing the testis. Hydrocele occurs as a smooth, pear-shaped swelling, fluctuating when pressed, devoid of pain or tenderness, but sometimes causing a slight uneasiness from its weight.

The quantity of serous fluid in the sac is usually from 6 to 20 oz., but it occasionally exceeds 100 ounces. Hydrocele may occur as a result of acute inflammation, but it most commonly comes on without any apparent local cause. It is most frequently met with about or beyond the middle period of life, and generally in persons of feeble power, or with a tendency to gout; sometimes, however, it occurs in young children, either in the same form as in adults, or as what is termed *congenital hydrocele*, when the communication between the tunica vaginalis and the abdominal peritoneum is not obliterated, as it normally should be.

The treatment is divided into the *palliative* and the *curative*. By the former, the surgeon relieves the present annoyance of his patient, while by the latter he aims at the

permanent removal of the disease. The palliative treatment consists in the use of suspensory bandages, evaporating and discutient lotions, and tapping with a fine trochar. Tapping seldom gives more than temporary relief, the swelling usually again regaining its former bulk in three or four months.

The curative treatment consists in setting up sufficient inflammation in the tunica vaginalis to destroy its undue secreting faculty. This is most commonly done by the injection of tincture of iodine into the sac, or by the passage of a fine seton or an iron wire (as proposed by Dr. Simpson) through it.

HYDROCEPH'ALUS. Under this term, which literally means *water in the head*, are included three distinct diseases—viz., acute hydrocephalus, chronic hydrocephalus, and spurious hydrocephalus, or, as Dr. Marshall Hall termed it, hydrocephaloid disease.

By *acute hydrocephalus* is signified inflammation of the brain as it usually occurs in scrofulous children. The name is not a good one, because it merely refers to a frequent effect of the disease, and not to its cause or essence; and because, further, a similar effect may result from other morbid conditions; it is, however, so universally adopted, that it would be inexpedient to change it. The disease is one of so dangerous a nature, that it is of the greatest importance to detect it in its earliest stage, and even to look out for indications of its approach. The premonitory symptoms (which, however, do not occur in all cases) consist chiefly in a morbid state of the nutritive functions. The appetite is capricious, the tongue foul, the breath offensive, the belly enlarged, and sometimes tender, and the evacuations unnatural; and the child is heavy, languid, and dejected, and becomes either fretful and irritable, or drowsy and listless. Restless sleep attended by grinding of the teeth or moaning, a frequent sudden scream, clenching of the fists, and a turning in of the thumb towards the palm of the hand, are also important premonitory warnings.

After these symptoms have lasted for some days, severe pain in the head comes on, it is generally of a sharp shooting character, recurring at intervals, and often during sleep, and causing the child to shriek in a very characteristic manner. Coma or morbid drowsiness now supervenes, and the shrieking is replaced by moaning. Vomiting is a frequent concomitant of this stage of the disease. In this first stage of hydrocephalus, which most commonly lasts two or three days, the pulse is rapid, and the symptoms generally are those of excitement. In the second stage, the pulse becomes irregular, variable, and often slow. General heaviness and stupor come on. The light, which annoyed the child in the first stage, is no longer a source of annoyance; the pupils become dilated, the power of sight becomes imperfect or lost, and squinting is almost always to be observed. The little patient now lies on his back in a drowsy condition; and at this period spasmodic twitchings, convulsions, or paralysis may come on. The excretions are passed unconsciously. This second stage may last a week or two, and is often attended by deceptive appearances of amendment, the child not unfrequently regaining the use of its senses for a day or two, but then relapsing into a deeper stupor than before. The symptoms in the third or last stage, which may last only a few hours, or may extend to a fortnight, are very similar to those in the second, except that the pulse again becomes very rapid, beating sometimes so quickly that it can scarcely be counted, and gradually gets more and more weak, till the patient expires. The characteristic appearances after death are softening of the central part of the brain, with the effusion of serous fluid, usually to the extent of several ounces, into the ventricles; and a tubercular deposit, in the shape of small granules, upon or between the membranes of the brain.

The only disorder with which acute hydrocephalus can easily be confounded is infantile remittent fever; but we have not space to notice the various points which enable us to discriminate between these two complaints. Acute hydrocephalus is essentially a disease of childhood; it scarcely ever occurs after the twelfth year. Half the cases that occur are in children between three and six years of age.

As the treatment should be left entirely to the physician, it is unnecessary to notice it further than to state that strong antiphlogistic remedies—such as cold to the head, leeching, and active purging—applied in the first stage of the disease, yield the most satisfactory results; yet under this treatment, three cases out of four are lost.

Chronic hydrocephalus is a perfectly distinct disease from acute hydrocephalus; while the latter is an inflammation, the former is a dropsy. In chronic hydrocephalus, a watery fluid collects within the skull, before the bones have united to form the solid brain-case, and by pressure outwards causes the bones to separate, and increases the size of the head sometimes to an enormous extent. Thus Dr. David Monro relates the case of a girl six years old whose head measured 2 ft. 4 in. in circumference. While the skull is rapidly enlarging, the bones of the face grow no faster than usual, and the great disproportion of size between the head and the face is at once diagnostic of the disease. This disorder sometimes commences before birth, and almost always in early childhood, before the fontanelles and sutures of the skull have closed. In some rare cases, it has occurred later, as, for example, at seven or nine years old, and the closed sutures have opened under the augmenting pressure. When the sutures will not yield, death from pressure on the brain speedily ensues. Most children with chronic hydrocephalus either recover or die in infancy; but a few survive, bearing their complaint to adult life, or even to old age. Blindness, deafness, palsy, and idiocy—one or more—

are commonly associated with this disease, but occasionally the intellect and senses are sufficiently perfect for the ordinary requirements of social life.

The treatment may be attempted by internal remedies or by surgical appliances. The medical treatment most worthy of trial consists in the administration of diuretics, purgatives, and especially mercury, which may be given in the form of calomel in minute doses, and applied as ointment externally. The surgical expedients are bandaging and puncturing the head. The former has in some cases effected a permanent cure; the latter has in many cases certainly prolonged life, although the disease has finally conquered. Neither of these means is applicable after the bones of the skull have united.

This disease occasionally occurs in adult or in advanced life, after enlargement of the head has become impossible. Stupor, paralysis, and an inability or unwillingness to speak, are in these cases the most prominent symptoms. Dean Swift's death was due to this disease, and it is recorded that during the last three years of his life he remained in a state of silence, with few and slight exceptions.

Spurious hydrocephalus—the *hydrocephaloid disease* of Dr. Marshall Hall—resembles acute hydrocephalus in many of its symptoms, and has often been mistaken for it. Instead, however, of being an inflammatory disease, it is a disease of debility, and is due to a deficient supply of blood to the brain. The following are, according to Watson, the distinctive characters of this spurious hydrocephalus: the pale, cool cheek, the half-shut, regardless eye; the insensible pupil; the interrupted, sighing respiration; and the state of the unclosed fontanelle. If the symptoms are those of acute hydrocephalus, the surface of the fontanelle will be convex and prominent; while if they are due to spurious hydrocephalus, and originate in emptiness and want of support, the fontanelle will be concave and depressed. The remedies in this disease, which readily yields to treatment, are nourishing diet, small doses of wine or even of brandy in arrow-root, decoction of bark, ammonia, etc.

HYDROCHARI'DEÆ, or HYDROCHARIDA'CEÆ. See ANACHARIS and VALLISNERIA.

HYDROCHLOR'IC ACID (symbol, HCl; equivalent, 36.5) is one of the most important compounds in inorganic chemistry. If the two gases which enter into its composition (hydrogen and chlorine) be mixed in equal volumes, they will remain without action upon each other, if kept in the dark; but as soon as they are brought into direct sunlight, they unite with a loud explosion, and hydrochloric acid gas is the result. The principal characters of this gas are that it is colorless, intensely acid, irrespirable, and even, when largely diluted, is very irritating to the lungs and eyes, and very injurious to vegetation; that it is heavier than air (its specific gravity being 1.2474, air being taken at 1.000); that it can be condensed into a colorless liquid; that it is very soluble in water, and that it is neither combustible nor a supporter of combustion. When allowed to escape into the air, it produces white fumes, by condensing the atmospheric moisture. If the air be previously dried, no such fumes are apparent.

The solutions of this gas in water form the acid which was first known as *spirit of salt*, then as *muriatic acid*, and which is now termed *hydrochloric* or *chlorhydric acid*. A saturated watery solution of this gas at 40° has a specific gravity of 1.21, and consists of 1 equivalent of the gas dissolved in 6 equivalents of water. It forms a colorless, fuming liquid, which acts as a caustic. On heating it, the gas is evolved abundantly until the temperature slightly exceeds 212°, when there distills over a diluted solution, having a specific gravity of 1.1, and consisting of 1 equivalent of the gas, and 16 equivalents of water. It is to these solutions of hydrochloric acid that the term *hydrochloric acid* is far more commonly applied than to the gas itself. They possess the ordinary characters of an energetic acid, and neutralize the strongest bases. The neutralization is, however, not in consequence of the acid combining with the oxide, but is due to the simultaneous decomposition of the acid and of the oxide, water and a metallic chloride being formed. If M represents the metal, the reaction is expressed by the equation $MO + HCl = MCl + HO$. All metals which, at a red heat, decompose water, also decompose this acid, and cause an evolution of hydrogen, the reaction being expressed as follows: $M + HCl = MCl + H$.

Hydrochloric acid gas is a common gaseous volcanic product. Free hydrochloric acid, in a very dilute form, is also a constituent of the gastric juice of man and animals, and plays an essential part in the digestive process.

Commercial *muriatic acid*—to use the name employed by manufacturing chemists—is made by heating, in iron cylinders, common salt (chloride of sodium) and oil of vitriol (hydrated sulphuric acid), and condensing the evolved gas in water contained in a series of stoneware Wolffian bottles (q.v.), the reaction being explained by the equation:

Chloride of Sodium.		Oil of Vitriol.		Hydrochloric Acid.		Sulphate of Soda.
$ClNa$	+	HO,SO_3	=	HCl	+	NaO,SO_3

This commercial acid may contain various impurities—as, for example, iron (which gives it a bright deep yellow color), the chlorides of sodium and arsenic—the latter being derived from the oil of vitriol—sulphuric and sulphurous acids, chlorine, etc.; from which it can be purified to a great extent by dilution and redistillation. "If pure," says prof. Miller, "the acid should leave no residue when evaporated; on satur-

ating it with ammonia, it should give no precipitate of oxide of iron; sulphureted hydrogen should produce no turbidity in it, which would be the case if arsenic, free chlorine, or sulphurous acid were present; and on dilution with three or four times its bulk of water no white cloud of sulphate of baryta should be produced by the addition of chloride of barium."

The presence of hydrochloric acid, or of the soluble chlorides in solution, may be detected by the addition of a few drops of a solution of nitrate of silver, which occasions the formation of a white curdy precipitate of chloride of silver, which is insoluble in nitric acid, but dissolves in a solution of ammonia.

Liquid hydrochloric acid (under the name of spirit of salt) was known to the alchemists. Hydrochloric acid gas was discovered by Priestley in 1772; and Davy, in 1810, ascertained that it was composed of chlorine and hydrogen.

In many of their properties, the analogous acids, hydrobromic, hydrofluoic, and hydriodic acids resemble hydrochloric acid.

HYDROCOTYLE, a genus of umbelliferous plants, having simple umbels, entire acute petals, and fruit of two flat orbicular carpels, with five more or less distinct threadlike ribs, and no vittæ. The species are numerous, generally more or less aquatic, widely distributed. One only is a native of Britain, *H. vulgaris*, which grows in marshy places, and is called marsh pennywort from the orbicular leaves, and sometimes white-rot, sheeps-bane, flowk-wort, etc., from a notion that it is injurious to sheep which eat it, causing foot-rot or fluke-worm—effects rather to be ascribed to the marshy situations in which it grows.

HYDROCYANIC ACID (C_2N,H or Cy,H), known also as prussic acid, from its having been first obtained by Scheele, in 1782, from the substance known as Prussian or Berlin blue, is of almost equal interest to the chemist, the physician, and the toxicologist. We shall notice (1) its chemistry, (2) its medicinal value, and (3) its action as a poison, and its antidotes.

1. *Its Chemistry.*—Pure anhydrous hydrocyanic acid is a limpid volatile fluid, with a specific gravity of 0.697 at 64° F. It boils at 80°, and solidifies into a crystalline mass at 5° F. Its volatility is so great that if a drop be allowed to fall on a piece of glass, part of the acid becomes frozen by the cold produced by its own evaporation. It possesses a very penetrating odor, resembling that of peach-blossoms or oil of bitter almonds. It burns with a whitish flame, reddens litmus paper slightly (its acid properties being feeble), and is very soluble in water and alcohol. Pure hydrocyanic acid may be kept unchanged if excluded from light, which occasions its decomposition, and the formation of a brown substance known as paracyanogen.

Hydrocyanic acid is readily obtained by distillation from the kernels of bitter almonds, and many kinds of stone-fruit, from the leaves and flowers of various plants, and from the juice of the tapioca plant (*jatropha manihot*). Anhydrous hydrocyanic acid is obtained by the reaction of concentrated hydrochloric acid on cyanide of mercury.

The preparation of the dilute acid is, however, of much greater practical importance. The London, Edinburgh, Dublin, and United States pharmacopœias agree in recommending that it should be obtained by the distillation of a mixture of dilute sulphuric acid and ferrocyanide of potassium (known also as prussiate of potash). The distillate should contain nothing but hydrocyanic acid and water, so that, by the addition of more water, we can obtain an acid of any strength we please. Sometimes, however, a second, or even a third distillation is necessary. The dilute acid of the *Ph. Lond.* contains 2 per cent; that of the *Ph. Dub.* rather more; that of the *Ph. Edin.* contains 3.3 per cent; while what is known as Scheele's acid is very variable, but averages 4 per cent of the anhydrous acid.

The ordinary tests for hydrocyanic acid are 1, the peculiar odor; 2, the nitrate of silver test—there being formed a white precipitate of cyanide of silver, which is soluble in boiling nitric acid; 3, the formation of Prussian blue, by adding to the fluid under examination a solution of some proto and per-salt of iron, by then saturating with caustic potash, and finally adding an excess of hydrochloric acid; when, if hydrocyanic acid is present, we have a characteristic blue precipitate; 4, the sulphur test, which is the best and most accurate that has yet been discovered. Let the suspected liquid be acidulated with a few drops of hydrochloric acid; place it in a watch-glass, and let a second watch-glass, moistened with a drop of a solution of hydrosulphate of ammonia, be inverted over it; after a few minutes, let the upper glass be removed, and the moistened spot be gently dried. The whitish film which is left may consist merely of sulphur; when hydrocyanic acid is present, it consists of sulphocyanate of ammonia. Let this residue be treated with a drop of a weak solution of perchloride of iron, when, if hydrocyanic acid was present, a blood-red tint is developed, which disappears on the addition of one or two drops of a solution of corrosive sublimate. This is known as Liebig's test.

2. *Its Medicinal Uses.*—We are indebted to the Italians for the introduction of hydrocyanic acid in the materia medica; and it was first employed at the beginning of the present century. There are no cases in which it is so serviceable as in those affections of the stomach in which pain is a leading symptom, as in gastrodynia, water-brash, and

in cases of intense vomiting. Hence it is often useful in English cholera, when opium has completely failed. In pulmonary diseases it does not produce the good effects that were formerly ascribed to it; but it is sometimes useful in allaying spasmodic cough. It has been employed with advantage in chronic skin-diseases, to allay pain and irritation. A mixture of two drams of the dilute acid (of 2 per cent strength) with half a pint of rose-water, and half an ounce of rectified spirit, forms a good lotion. When given internally, the average dose is from 3 to 5 minims of the 2 per cent dilute acid, three or four times a day; it must be administered in some milk vehicle, such as simple water, or orange-flower water.

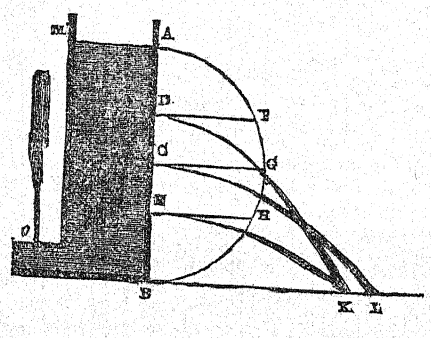
3. *As a Poison.*—Hydrocyanic acid is one of our most energetic poisons, and is frequently employed both in murder and suicide. When a *small* poisonous dose (about half a dram of the 2 per cent acid) has been taken, the first symptoms are, weight and pain in the head, with confusion of thought, giddiness, nausea (and sometimes vomiting), a quick pulse, and loss of muscular power. If death result, this is preceded by tetanic spasms and involuntary evacuations. When a *large* dose has been taken (as from half an ounce to an ounce of the 2 per cent acid), the symptoms may commence instantaneously, and it is seldom that their appearance is delayed beyond one or two minutes. "When," says Dr. A. S. Taylor, "the patient has been seen at this period, he has been perfectly insensible, the eyes fixed and glistening, the pupils dilated and unaffected by light, the limbs flaccid, the skin cold and covered with a clammy perspiration; there is convulsive respiration at long intervals, and the patient appears dead in the intermediate time; the pulse is imperceptible, and the respiration is slow, deep, gasping, and sometimes heaving or sobbing." The patient survives for a longer or shorter period, according to the dose. According to Dr. Lonsdale, death has occurred as early as the *second*, and as late as the *forty-fifth* minute.

The parts specifically affected are the brain and the spinal system. The affection of the respiratory system seems to be due to the influence of the acid on those parts of the nervous system from which the respiratory organs derive their nervous power. The immediate cause of death is, in most cases, the obstruction of the respiration; but in some cases, the stoppage of the heart's action.

Where the fatal action is so rapid antidotes are of comparatively little value. Chlorine, ammonia, cold affusion, and artificial respiration are the most important agents in the treatment. The first two should be used with great caution, and only by the medical practitioner. Cold affusion on the head, neck, and down the spine is a valuable remedy, and it is asserted that its efficacy is almost certain when it is employed before the convulsive stage of poisoning is over, and that it is often successful even in the stages of insensibility and paralysis. Artificial respiration (see RESPIRATION, ARTIFICIAL) should never be omitted. Dr. Pereira states that he once recovered a rabbit by this means only, after the convulsions had ceased, and the animal was apparently dead.

HYDRODYNAMICS treats of the laws of the motion of liquids; the flow of water from orifices and in pipes, canals, and rivers; its oscillations or waves; and its resistance to bodies moving through it. The term hydraulics is sometimes applied to the same subjects, from the Greek word *aulos*, a pipe. The application of water as a moving power forms the practical part of the subject.—In what follows, the illustration is taken from the case of water, but the principles established are true of liquids in general.

Efflux.—If three apertures, D, C, E, are made at different heights in the side of a vessel filled with water, the liquid will pour out with greater impetuosity from C than from D, and from E than from C. The velocity does not increase in the simple ratio of the depth. The exact law of dependence is known as the theorem of Torricelli; the demonstration is too abstruse for introduction here, but the law itself is as follows: "*Particles of fluid, on issuing from an aperture, possess the same degree of velocity as if they had fallen freely, in vacuo, from a height equal to the distance of the surface of the fluid above the center of the aperture.*" The jet from C, for instance, has the same velocity as if the particles composing it had fallen in vacuo from the level of the liquid to C. Now, the velocity acquired by a body in falling is as the time of the fall; but the space fallen through being as the *square* of the time, it follows that the velocity acquired is as the square root of the space fallen through. In the first second, a body falls 16 ft., and acquires a velocity of 32 feet. If E, then, is 16 ft. below the level, a jet from E flows at the rate of 32 ft.; and if D is at a depth of 4 ft., the velocity of the jet at D will be half the velocity of that at E, or 16 feet. In general, to



find the velocity for any given height, multiply the height by 2×32, and extract the square root of the product. This rule may be expressed by the formula $v = \sqrt{2gh}$, in which v signifies the velocity of the issue, g the velocity given by gravity in a second, or 32 ft., and h the height of the water in the reservoir above the orifice. This last quantity is technically called the *head* or *charge*.

That this theory of the efflux of liquids is correct, may be proved by experiment. Let the vessel, MB, have an orifice situated as at *o;* the water ought to issue with the velocity that a body would acquire in falling from M to the level of *o*. Now, it is established in the doctrine of projectiles (q.v.), that when a body, is projected vertically upwards with a certain velocity, it ascends to the same height from which it would require to fall in order to acquire that velocity. If the theory, then, is correct, the jet ought to rise to the level of the water in the vessel at M. It is found in reality to fall short of this; but not more than can be accounted for by friction, the resistance of the air, and the water that rests on the top in endeavoring to descend. When the jet receives a very slight inclination, so that the returning water falls down by the side of the ascending, ten in. of head of water may be made to give a jet of nine inches. A stream of water spouting out horizontally, or in any oblique direction, obeys the laws of projectiles, and moves in a parabola; and the range of the jet for any given velocity and angle of direction may be calculated precisely as in projectiles. The range of horizontal jets is readily determined by practical geometry. On AB describe a semicircle; from D, the orifice of the jet, draw DF perpendicular to AB, and make BK equal to twice DF; then it can be proved by the laws of falling bodies and the properties of the circle, that the jet must meet BL in the point K. If BE is equal to AD, the perpendicular EH is equal to DF; and therefore a jet from E will have the same range as that from D. Of all the perpendiculars, CG, drawn from the middle point C, is the greatest; therefore, the jet from C has the longest possible range.

The area of the orifice and the velocity of the flow being known, it is easy to calculate the quantity of water discharged in a given time. Thus, suppose the area to be 1 sq.in., and the velocity 20 ft. a second, it is evident that there issues in a second a cylinder or a prism of water 1 sq.in. in section and 20 ft. long, the content of which is 1×240=240 cubic inches. In any given time, then, as three minutes (=180 seconds), the discharge is 240×180=43,200 cubic inches.

It has as yet been assumed that the water in the vessel or reservoir is kept constantly at the same height, and that thus the velocity is constant. We have now to consider the case of a vessel allowed to empty itself through an orifice at the bottom. As the surface of the water sinks, the velocity of the discharge diminishes or is retarded; and when the vessel is of the same area from top to bottom, it can be proved that the velocity is *uniformly* retarded. Its motion follows the same law as that of a body projected vertically upwards. Now, when a motion uniformly retarded comes to an end, the space described is just half what the body would have passed over had it gone on uniformly with the velocity it had at the outset. Therefore, when the vessel has emptied itself in the way supposed, the quantity discharged is half what would have been discharged had the velocity been uniform from the beginning.

The "Contraction of the Vein."—When, by means of the area of the opening and the velocity thus determined, we calculate the number of cubic feet or of gallons that *ought* to flow out in a given time, and then measure the quantity that actually does flow, we find that the actual flow falls short of the theoretical by at least a third. In fact, it is only the central part of the jet, which approaches the opening directly, that has the velocity above stated. The outer particles approach from all sides with less velocity; they jostle one another, as it were, and thus the flow is retarded. In consequence of this want of uniformity in velocity and direction among the component layers of the jet, as they enter the orifice, there takes place what is called a "contraction of the vein" (*vena contracta*); that is, the jet, after leaving the orifice, tapers, and becomes narrower. The greatest contraction is at a distance from the orifice equal to half its diameter; and there the section of the stream is about two-thirds the area of the opening. It is, in fact, the section of the contracted vein that is to be taken as the real area of the orifice, in calculating by the theory the quantity of water discharged. If the wall of the vessel has considerable thickness, and the orifice is made to widen gradually inwards, in the proportions of the contracted vein, the stream does not suffer contraction, and the area of the orifice where it is narrowest may be taken as the actual area of discharge.

Adjutages.—It has as yet been supposed that the issue is by means of a simple opening or hole in the side or bottom of the vessel; but if the flow takes place through a short tube, the rate of discharge is remarkably affected. Through a simple opening, in a thin plate, the actual discharge is only about 64 per cent of the theoretical; through a cylindrical conducting-tube, or *adjutage*, as it is called, of like diameter, and whose length is four times its diameter, the discharge is 84 per cent. The effect is still greater if the discharge-tube is made conical both ways, first contracting like the contracted vein, and then widening. The effect of a conducting-tube in increasing the discharge is accounted for by the adhesion of the water to its sides, which widens out the column to a greater area than it would naturally have. It has thus a tendency to form a vacuum in the tube, which acts like suction on the water in the reservoir, and

increases the quantity discharged. The flow is more free if the orifice is in the bottom of the vessel, than in the side on a level with the bottom. If the discharge-tube is made to project inwards beyond the thickness of the walls of the vessel, the velocity is much impeded, owing to the opposing currents produced by the water approaching the opening.

Pipes.—When a conduit pipe is of any considerable length, the water issues from it at a velocity less than that due to the head of water in the reservoir, owing to the resistance of friction. With a pipe, for instance, of 1½ in. in diameter, and 30 ft. long, the discharge is only one-half what it would be from a simple orifice of the same diameter. The rate of reduction depends upon the diameter of the tube, its length, the bendings it undergoes, etc. The resistance to the flow of water in pipes does not arise properly from friction, as understood of solids, but from the adhesion of the water to the sides of the pipe, and from the cohesion of the watery particles among themselves; it makes little difference, therefore, whether an earthenware pipe, for instance, be glazed or not. Large projections form an obstacle; but mere roughness of surface is filled up by an adhering film of water, which is as good as a glaze. The resistance increases greatly with the narrowness of the pipes. Engineers have formulas, deduced in great part from experiment, for calculating the discharge through pipes of given length and diameter, and with a given head; but the subject is too complicated for introduction here. If water flowed in a conduit pipe without friction or other obstruction, so that its velocity were always equal to that due to the head of water, there would be no lateral or bursting pressure on the walls of the pipe; and if the pipe were pierced, the water would not squirt out. Accordingly, with a short tube or adjutage, which, instead of obstructing, increases the flow, there is not only no lateral outward pressure on the walls of the tube, but there is actually a pressure inwards. If a hole is made in the wall of a cylindrical adjutage and the one end of a small bent tube is inserted in the hole, while its other end is dipped in a vessel of water, the water will be sucked up the tube, showing the tendency that the adjutage has to form a vacuum. But when the velocity of discharge is diminished by the friction of a long pipe, or by any narrowing, bending, or other obstruction in the pipe, then that portion of the pressure of the head of water that is not carried off in the discharge, becomes a bursting pressure on the walls of the pipe. This pressure is unequal at different parts of the pipe. At the end where the water issues free and unobstructed, it is next to nothing, and gradually increases towards the reservoir, where it is equal to the difference between the head of water in the cistern, and the head due to the velocity with which the water is actually flowing in the pipe. The principle now explained accounts for the fact, that pipes often burst or begin to leak on the motion of the water in them being checked or stopped.

Resistance of Water to Bodies moving through it.—This is greatly affected by the shape of the body, which ought to have all its surfaces oblique to the direction of the motion. When a cylinder terminates in front in a hemisphere, the resistance is only one-half what it is when the cylinder terminates in a plane surface at right angles to the axis; and if instead of a hemisphere, the termination is an equilateral cone, the resistance is only one-fourth. If a globe is cut in halves, and a cylinder, whose length and the diameter of whose base are each equal to the diameter of the globe, is fixed between them; this cylinder with hemispherical ends experiences less resistance than the globe alone, the diminution being about one-fifth of the resistance to the globe. Also the resistance increases in a higher ratio than the simple one of the velocity. One part of the resistance arises from the momentum that the body has to give to the water it displaces. Moving at a certain rate, it displaces a certain quantity; moving at twice that rate, it displaces twice the quantity in the same time. But not only does it displace twice the number of particles of water; it also has to displace them with twice the velocity; the pressure of the resistance is thus not merely doubled, but quadrupled or squared. Similarly, when the velocity is tripled, the resistance arising from the simple displacement of water becomes nine times as great. Another part of the resistance of liquids to bodies moving in them is owing to the cohesion of the particles, which have not to be thrown aside merely as separate grains, but to be torn asunder. In addition to this, when the velocity is considerable, the water becomes heaped up in front, and depressed at the other end from not having time to close in behind, thus causing an excess of hydrostatic pressure against the direction of the motion. Owing to the combination of these causes, the real law of the increase of resistance is difficult to investigate, and the results of experiments are not a little discordant. See WATER-POWER, WAVES.

HYDROFLUORIC ACID. See FLUORINE.

HYDROFLUOSILICIC ACID. See FLUORINE, *ante.*

HYDROGEN (symbol H, equiv. 1), so called from the Greek words *hydōr*, water, and *gennāo*, to generate, is an elementary substance, which exists as a colorless and inodorous gas (regarded as permanent till 1878). One of its most striking peculiarities is its specific gravity, it being the lightest of all known bodies. Assuming the weight of a given volume of atmospheric air to be 1, the weight of the same volume of hydrogen under similar conditions is 0.0692; hence hydrogen is 14½ times lighter than atmo-

spheric air; while, on the other hand, it is 241.573 times lighter than platinum, the heaviest body known. Its refractive power is greater than that of any other gas, and is more than 6 times as great as that of atmospheric air. It is combustible; that is to say, it is capable of combining with oxygen, and developing light and heat. When a lighted taper is passed up into an inverted jar of hydrogen, the gas burns quietly with a pale-blue, scarcely visible flame, and the taper is extinguished. The flame only occurs at the line of junction of the hydrogen and the external air. If the hydrogen be mixed with air or oxygen prior to the application of the taper, the whole mixture is simultaneously inflamed, and there is a loud explosion, which is most violent when 2 volumes of hydrogen are mixed with 1 volume of oxygen, or with 5 volumes of atmospheric air. The hydrogen and oxygen in these cases combine to form watery vapor or steam, which suddenly expands from the high temperature attendant on the combustion, but immediately afterwards becomes condensed; this condensation causes a partial vacuum, into which the surrounding air rushes, and by the collision of its particles produces the report. At ordinary temperatures, water dissolves rather less than 2 per cent of its volume of hydrogen. Hydrogen was liquefied for the first time in 1878, and even solidified (see GASES). Pure hydrogen, though it cannot support life, is not poisonous, and when mixed with a sufficient quantity of atmospheric air or oxygen, may be breathed for some time without inconvenience.

Hydrogen does not possess very marked chemical properties. The only substances with which it combines directly at ordinary temperatures are chlorine and oxygen. Hydrogen and chlorine, mixed together, and exposed to direct sunlight, combine with explosion; in diffused daylight, they gradually unite; but in the dark do not act on one another. Hydrogen and oxygen do not combine spontaneously even in direct sunlight, but require the presence of a red-hot solid, of flame, or of spongy platinum.

It is generally stated that hydrogen does not exist naturally in a pure or uncombined state, but Bunsen recognized its presence in variable proportions in the gases evolved from the solfataras of Iceland, and it will probably be detected in other localities where similar geological relations hold good. In combination with oxygen, as water, it not only forms a very considerable part of the earth, and of the atmosphere, but enters largely into the structure of every animal and vegetable organism. It is an essential ingredient of many inflammable minerals, such as coal, amber, and petroleum; and of certain gases, such as marsh gas, ammonia, and hydrosulphuric acid (or sulphureted hydrogen). It likewise enters into the composition of a large number of manufactured substances and products used in the arts, medicine, etc., as for instance, sal-ammoniac, starch, sugar, vinegar, alcohol, olefiant gas, aniline, indigo, morphia, strychnia, hydrocyanic acid, etc.

There are numerous ways in which hydrogen may be prepared, but the usual and most convenient process is by the action of diluted sulphuric acid on zinc. About half an ounce of granulated zinc is placed in a retort, and a dilute acid, prepared by gradually mixing an ounce of oil of vitriol with six ounces of cold water, is poured on the zinc. Hydrogen gas is rapidly evolved in great abundance, but the first portions should not be collected, since they are mixed with the atmospheric air which was contained in the retort. The rest of the gas may be collected in the ordinary way over water. In this process the zinc takes oxygen from the water, and forms oxide of zinc, which combines with the sulphuric acid, forming sulphate of zinc, which remains in solution, while the hydrogen of the decomposed water escapes. The reaction is shown in the formula, $Zn + HO,SO_3 = ZnO,SO_3 + H$. A precisely similar reaction ensues if we use iron in place of zinc, but in this case the gas is generally less pure.

Hydrogen gas, under the name of combustible air, was obtained in the 16th c. by Paracelsus by treating certain metals with dilute acids, and was more or less known to Boyle and others; but Cavendish, in his paper on "Factitious Airs," published in the *Transactions of the Royal Society* for 1766, was the first to describe accurately the properties of this gas, and the methods of obtaining it; hence he is usually mentioned as its discoverer.

HYDROGEN, BINOXIDE OF (symb. HO_2, equiv. 17), is a colorless liquid of a syrupy consistence, with a specific gravity of 1.45 (water being 1), and a peculiar odor, something like that of very dilute chlorine. It bleaches vegetable colors, and when applied to the tongue or the skin produces a white spot, and excites considerable pain. From the readiness with which it gives off its oxygen, it is a powerful oxidizing agent. The method of preparing it is complicated and difficult. This substance was discovered in 1818 by Thenard, who termed it oxidized water. Dr. B. W. Richardson, an eminent London physician, has lately examined its value (in solution) as a therapeutic agent, and has found it to be of extreme use in whooping-cough, in certain forms of rheumatism, and (as a palliative) in the last stages of consumption.

HYDROG'RAPHY (Gr. *hydōr*, water, *graph-*, to write) is a description of the surface waters of the earth, particularly of the bearings of coasts, of currents, soundings, islands, shoals, etc., and of anything the knowledge of which may be useful for purposes of navigation. It consequently includes the construction of charts, maps, etc., in which these particulars are detailed. It is, in fact, to the sea what geography is to the land. The first step in the erection of hydrography into a science was made in the

15th c. by Henry the navigator, who was the first to construct a sea-chart worthy of the name. Among the maritime nations of Europe it is now made a matter of prime concern; the hydrographic office being an important branch of the naval administration. The head of the hydrographic department in the British service is usually a capt. in the royal navy. The officers surveying in different parts of the world send their observations, soundings, etc.; and it is the business of the hydrographer to consolidate these into available maps. The hydrographer receives £800 a year in addition to his half-pay. In proof of the value attached to these admiralty charts among the marine of England and even of foreign nations, it may be mentioned that many thousand charts, besides books of sailing directions, are sold annually.

HYDROG'RAPHY (*ante*). The science of hydrography received a new impulse from the celebrated capt. James Cook, of the English navy, who introduced what is known as running surveying, but his system has been greatly improved. The commencement of Cook's hydrographic surveys was in 1759, when he was master of the frigate *Mercury*, stationed at Quebec with the squadron co-operating with gen. Wolfe. He commenced a series of observations of the St. Lawrence river, which were continued until he was able to publish a chart of the river from Quebec to the Atlantic ocean. In 1763 he was sent out to survey the coast of Newfoundland, and in 1764 he received the appointment of surveyor of the coast of Newfoundland and Labrador. Wherever he was ordered he continued his hydrographic observations until the year of his death, 1779. The French had been observers of his operations, and in 1785 La Perouse was sent with two ships and a corps of scientists to visit the n.w. coast of America and to explore other parts. He made important observations there, and also on the n.e. coast of Asia. After spending two years and a half he went to Botany Bay, after which he was never heard from, except that information was obtained seven or eight years afterwards which made it probable that the ships were wrecked on a coral reef on the coast of Mallicollo. But La Perouse had sent duplicates of charts and journals up to the time of his arrival at Botany Bay. The navigating officer of the expedition, Beautemps-Beaupre, sent out to search for La Perouse in 1791 under the command of D'Entrecasteaux, wrote a work on marine surveying, which was published in an appendix to the narrative of the voyage (1808). This, however, had been preceded by Alexander Dalrymple's essay on marine surveying, published in 1771. Beautemps-Beaupre was placed in charge of the survey of the French coast, where he trained a number of hydrographers, the commencemant of a corps of engineers for future exploration and surveying. Most civilized nations now have their governmental hydrographic offices, and numbers of officers and men are engaged in making surveys, but England leads all other nations in this direction, having made accurate surveys of her domestic and foreign coasts, and many of those of other nations. The most important, perhaps, of all the expeditions ever sent out by Great Britain was that of the *Challenger*, which sailed from Sheerness on Dec. 7, 1872, and returned to Spithead on May 24, 1876, having during this time traversed a distance of more than four times the equatorial circumference of the earth, and established 362 observing stations along the course traversed. The objects, however, of this expedition extended, in many respects, beyond the observation of the configuration of the floor of the ocean or of its coast line; had regard to many botanical, zoological, and geological questions. During the first year the Atlantic was crossed six times, and a diversion made from Bermuda to Halifax and back again to make observations upon the gulf stream. The ship then went to the cape of Good Hope, and from thence southward toward the Antarctic ice barrier, and after taking observations along its margin proceeded to Melbourne, Sidney, and New Zealand. Then the western part of the great area of the Pacific was examined and the adjacent part of the Malay archipelago. On leaving this for Japan, at a point n. of New Guinea, the deepest sounding of the expedition was made, and the deepest reliable sounding, it is claimed, that has yet been made, viz., 4,475 fathoms, or more than five miles. From Japan she steered due e. as far as the meridian of the Sandwich islands; thence to that group; thence to Otaheite, as far beyond the equator; from Otaheite to cape Horn; thence to Valparaiso and back through the straits of Magellan, to the Falkland islands, to Montevideo, and thence eastward half-way across the Atlantic to complete some work partly done during the first year; thence due n. in the meridian of Madeira as far as the equator; thence n.w. at some distance from the coast of Africa, following the middle line of the north Atlantic, past the Azores, and thence home. At each of the observing stations a sounding was taken to determine the exact depth; the bottom temperature was ascertained, and a sample of bottom water obtained. Some of the bottom, from an ounce to a pound, was also brought up, and at most of the stations the temperature of the water at several different depths was taken, and also a fair sample of the bottom fauna obtained by the dredge. The direction and rate of the surface water was determined, and at times attempts were made to determine the direction and velocity of the water at different depths. In addition to this, meteorological and magnetic observations were regularly taken and recorded. The work accomplished included, among many other results, the determination of the depth and configuration of the ocean basins. But little was previously known of this except what had been obtained in surveying lines for telegraph cables. Facts had been observed during these cable-line surveys which were supposed to

be exceptional, but the soundings of the *Challenger*, and those of the U. S. ship *Tuscarora* and the German *Gazelle*, have shown them to be general. See SEA SOUNDING, DEEP SEA, *ante*. The methods practiced in hydrography vary with circumstances. When the advantages of good triangulation exist, a hydrographic chart can be constructed with great accuracy. The principles involved are the same as those in geodetic surveying or leveling, the vertical measurements being taken with a sounding line instead of a rod, and the element of time employed to approximate horizontal distances. A boat is started at a certain point which has been determined by triangulation, and takes a course towards another point whose position is also known. The boat is then propelled with as near a uniform rate of motion as possible, and soundings are taken in succession at regular intervals during the transit, and recorded. The plotting of this line will, of course, give the depths of water all along its course at the time it was taken. A tide gauge, which gives the state of the tide at the time, will also determine the depths of the soundings at mean low water. A number of "sounding lines," as these courses are called, having been run across the bay or harbor, or whatever sheet of water is being surveyed, and of such a number as may be thought necessary, which will depend upon the nature of the bottom, the data are obtained for the plotting of a chart. If the bottom is known to be comparatively even, and no rocks or steep slopes have been found, and if it be convenient to do so, the lines may all be run in parallel directions. But when the bottom is quite uneven, and there are rocks or sunken vessels, these parallel lines should be crossed, as nearly at right angles as possible, by another series of parallel lines, and all should be as close together as practicable. When the shore cannot be used for triangulation a base line must be established, as well as circumstances will allow, by anchored boats whose distance apart may be computed by the time which sound is found to travel from one to the other; or, if the water be not too rough, by the average time it takes to row in both directions from one boat to the other; or a cord may be used to measure a distance too great. Sounding lines may then be run in different directions from these points of observation, between points which can be established, or in directions towards prominent objects on shore, and the distance traversed estimated by such means as may be most convenient, according to the resources of the engineer. It is often necessary, especially when it is impossible to run the sounding boat with uniform motion, or where the bottom is quite uneven, or the position of rocks is to be determined, to take two observations on shore with theodolites simultaneously with any special soundings, the time being determined by a ball or flag signal, or a flash made from the boat. The angles being taken between the point designated by the signal and another established point, its locality is readily established. The hydrography of the United States is in charge of the coast survey. There is a coast survey office and a hydrographic office, the latter established in 1866. See COAST SURVEY, GEODESY, and TRIANGULATION.

HY'DROIDS, marine animals which have been variously classified by naturalists because of the extreme difficulty of studying their natural history. Modern classification makes them a sub-class, Hydroida, in the class Hydrozoa, sub-kingdom Cœlenterata, the representative of Cuvier's Radiata. The Hydroida possess a great deal of interest because remaining so long unrecognized in some of their phases of life. In one stage of their existence they so much resemble sea plants that for a long time they escaped recognition. Patient labor, however, has at last placed them in their proper relations. These hydroids exist in compound colonies of alternate generations, one kind having the office of feeding the community, the other of reproduction. The feeding hydroids are usually fixed, or attached to some object, and proceed from eggs of the reproductive, or medusæ hydroids, the latter in turn growing from buds produced by the former. The medusæ hydroids sometimes remain attached to the stem, or become free-swimming medusæ. The body of the nutritive hydroid is usually supported by a stem of variable length, but may rest immediately upon the bottom. From one individual buds appear and produce branching colonies of hundreds or thousands, often having a height of 15 or 20 inches. The reproductive hydroids are sometimes developed into perfect medusæ before leaving the parent stem, but they usually break away before attaining their perfect state. Some buds never become much developed, and are called sporosacs. These usually remain attached, but attain sexuality and reproductive power. The free-swimming medusæ often grow 9 or 10 in. in diameter, but many of them, it is said, remain very small, seldom attaining a diameter of more than an inch. See ACALEPHÆ; GENERATIONS, ALTERNATION OF; ZOÖLOGY, *ante*.

HY'DROMANCY. See DIVINATION.

HYDROMA'NIA. See PELLAGRA and SUICIDE.

HYDROM'ETER. See AREOMETER.

HY'DROMYS, a genus of rodent quadrupeds, of the family *muridæ*, of which there are only two known species, very similar to one another, natives of Tasmania. They have two incisors and four molars in each jaw. They are called beaver rats in Tasmania; are nocturnal and very shy; inhabit the banks of both fresh and salt water, and swim well. The largest species is twice the size of a common rat. One of them has the belly white, the other yellow.

HYDROP'ATHY, or HYGIEN'IC MEDICINE, popularly termed the water cure. Under the head of baths and bathing (q.v.), an account has been given of the bath in general, as a means of preserving health. We have here to speak of water in its manifold uses as an engine in the cure of disease, and as forming a principal element in that combination of hygienic appliances which goes to make up hydropathy as at present practiced. (In accordance with the plan followed in other cases of the kind, the view exhibited is that of an adherent of the system.)

The efficacy of water, in the cure of numerous forms of disease, has long been recognized. Water was largely employed by Hippocrates, the "father of medicine," more than 2,300 years ago, in the treatment of many kinds of disease; and along with a regulated diet, and an implicit belief in the *vis medicatrix naturæ*, it appears to have formed the chief element in his medical armory. Horace has enshrined the memory of Antonius Musa, the hydropathic physician of the emperor Augustus (Epist. i. 15). Both Celsus and Galen—who flourished, the one about 50 years B.C., and the other in the 2d c.—speak favorably in their writings of the use of water in the cure of disease, regarding it as of high value in the treatment of acute complaints, particularly of fevers. Throughout the middle ages, likewise, many physicians of name, including Aetius and Paulus Ægineta, and the more celebrated Paracelsus, were advocates of the remedial virtues of water; all of them, however, having faith in its uses in the treatment rather of acute than of chronic disorders. In 1723 Nicolo Lanzani, a Neapolitan physician, published a learned treatise on the subject. In our own country, about the beginning of the 18th c., sir John Floyer and Dr. Baynard made a large use of water. Their conjoint work, denominated *Psychrolousia*, or the "History of Cold Bathing, both Ancient and Modern," is replete with quaint learning and practical shrewdness and sagacity. But the most able and scientific among the older treatises that have appeared in England on the subject of the water treatment, is the work of the well-known Dr. Currie (q.v.), the biographer of the poet Burns, published in 1797, and entitled *Medical Reports on the Effects of Water, Cold and Warm, etc.* In this work, Dr. Currie recommends the cold affusion in typhus and other fevers, and gives practical directions in regard to the cases and the times when it may be used with advantage. Eminent physicians of the present day have admitted that these views, so far as they went, were as scientific in principle as they were novel in their application; but the practice founded on them was considered too dangerous by Currie's contemporaries, and fell into speedy neglect. It is worthy of remark that Currie appears to have limited his use of water to acute ailments exclusively.

We have thus seen that up to the beginning of the present century, by some of those who employed it as a curative agent, water was used in the treatment of acute, and by others of chronic diseases; by some as an internal agent alone, by others as an external application in the various forms of the bath, but never in all the manners combined. This combination was first effected by the original genius of Vincent Priessnitz, a Silesian farmer, with whom began a new era for the water-cure. It was owing, we are told, to his successful treatment of more than one bodily injury which he had sustained in his own person that, about the year 1820, Priessnitz became so fortified in his convictions as to the curative powers of water as to devote himself to employ it medically in the cure of others. Beginning with the external application of water for trifling diseases among the poor of his neighborhood, he gradually undertook an extended range of cases, and multiplied the modes of administration, introducing the wet compress, the douche bath, partial baths of all kinds, the sweating process, the wet sheet, together with copious drinking of pure water. In addition to water in all these forms, he insisted on the value of exercise, diet, fresh air, and mental repose, in the cure of disease; thus practically calling to his aid the entire resources of hygiene, and establishing by a simple, yet thoroughly original combination, nothing less than a new system of medical treatment. As to the success which attended Priessnitz's practice, it is a historical fact that of 7,500 patients, who had gone to Gräfenberg for advice and treatment, up to the year 1841, or within the space of about 20 years, there had been only 39 deaths, and some of these, according to the registry of the Austrian police, "had died before commencing the treatment, while some others were reported in a forlorn state before anything was attempted." It is to be regretted, however, that the founder of the new system was not himself an educated physician, so that he could have understood better the philosophy of his own practice, and explained it more correctly. He would not have called his system the "water-cure," a name scientifically one-sided and incomplete, and therefore misleading. It is equally to be regretted that many of the immediate followers of Priessnitz, while destitute of his remarkable sagacity and genius, should have been no better furnished than himself with a scientific knowledge of disease and general professional culture.

In spite of all drawbacks, however, the undoubted merits of hydropathy at length called to its defense many men of standing in the profession, who, allowing for some of its early extravagances, stepped forth to explain it scientifically, and pressed it on the acceptance of their brethren; and from their advocacy has sprung up in England a school of hydropathic physicians, the philosophy of whose plan of treatment we shall now briefly describe.

Physiology teaches us that the various organs of our bodies cannot be kept in a

healthy state without the observance of certain regulations called the primary "laws of health." When these are broken, the result to the offender is disease in one of its many forms. Until the appearance of hydropathy, physicians attempted to correct the evil thus caused—and the great majority do so still—by the administration of one or other of the drugs which go to form the medical repertory known as the pharmacopœia; and the argument on which this practice has been based is the very simple one, that experience has proved the medicine or medicines to be efficacious in a large proportion of similar cases. Hydropathy proceeds according to a very different method. Taking as his central maxim the principle first propounded by Hippocrates, that it is nature's own strivings after health (*vis medicatrix naturæ*) that really cure the patient when he is cured, the function of art being mainly to remove obstacles, the hydropathic physician avoids using all means with whose effects he is not thoroughly conversant, or which may, at least, interfere with nature's own operations. Hence, as a rule, he eschews the use of drugs, and betakes himself to those more simple natural agents which, in their totality, receive the name of hygiene. The conditions of health, as unfolded by physiology, may be briefly stated to consist of five necessary requirements—air, exercise, water, diet, and nervous repose. These are undeniably essential to the preservation of health; no human being can possibly continue in a fair state of health when deprived of the just proportion of any one of them. This proposition, which may be regarded as axiomatic, forms the starting-point of hydropathy in the cure of disease. Admitted that certain agencies are necessary to the preservation of health, the hydropathic principle is simply this, that the very same agencies, infinitely modified of course according to the requirements of each particular case, and generally much intensified, are not only the safest, but by far the surest means of curing chronic disease; or, to put it more correctly, are the best means which can be brought to nature's assistance for enabling her to effect a cure herself.

Here it is proper to explain what is meant by saying that the natural agents of health are *intensified* when they are used, not for the preservation of health, but the cure of disease; or, in other words, when we pass from natural hygienics to natural therapeutics. Take the element of exercise, for instance, one of the most powerful hydropathic agencies. Every one knows, although but few act systematically on the knowledge, that a certain amount of exercise is necessary to maintain the body in health; the hydropathic doctrine, accordingly, is, that in the cure of chronic disease, this exercise must be intensified—increased to the full extent which the patient's strength will warrant. So, again, as to the use of water: a certain amount of pure water, used externally and internally, is also necessary to the maintenance of health; hydropathically, a much more liberal use of the same element in both ways is necessary to the cure of disease. The reader's special attention is called to this, which in fact is the very kernel of the hydropathic theory.

Let us now explain more in detail how and in what cases hydropathy employs the agents on which it relies. Diseases may, for general purposes, be divided into two great classes: those in which the physician is called on to lower or *reduce* to the standard of health; and those in which the object of his endeavors is, on the other hand, to assist in *elevating* to the same standard. In the former category, range themselves all those diseases which are marked by a plethoric or inflammatory type—by an overplus of maldirected strength in the economy; in the latter, those distinguished by a corresponding diminution in the vital powers. It may be truly affirmed, that to rectify both these abnormalities, and to restore the equilibrium of health, is the great object of medical treatment. The ordinary practice seeks to achieve this object mainly, in both instances, by means of drugs, respectively adapted to the two classes, and tending to lower in the one case and to exalt in the other. The hydropathic practice, with the same object in view, employs, as already stated, the natural remedies—air, exercise, water, diet, and repose.

Thus, in dealing with acute and plethoric complaints, and the whole order of diseases ranging themselves under the former of the divisions just indicated, water is the element which enacts by far the most conspicuous part, and the application of it most serviceable in these cases is the *wet sheet* or *pack*. Indeed, the discovery by Priessnitz of this application of water was perhaps the most important contribution which he made to the new system of which he was the practical founder, inasmuch as it at once supplied one of the most powerful and at the same time one of the safest methods of combating almost every form of acute disease. This, the most distinctive of hydropathic appliances, may be thus described: Over the mattress of a bed or sofa is extended a stout blanket, and on this is spread a linen sheet, well wrung out of cold water, so that it is only damp. On this the patient is laid, and immediately enveloped tightly with a heavy weight of blankets upon him, tucked in so closely as to completely exclude all air. The body's natural heat, acting on the damp linen, generates vapor almost immediately, and the patient forthwith finds himself, not in a cold, but in a comfortably warm vapor bath—in a novel, but by no means unpleasant form of body poultice. The effects of this process on the economy seem to be plain enough. It is clear, in the first place, that the pores of the skin, so numerous and performing so important a function, must thereby be thoroughly cleansed, and the blood itself depurated; with the equalization of temperature over the entire surface of the body, will follow a cor-

responding equalization in the distribution of blood throughout the system, thereby relieving internal congestions wherever occurring; and lastly, from the soothing effects on the nervous system, and the allaying of all irritation, must result not only the alleviation of pain, but that lowering of the heart's action, and with it of the circulation of the blood, of such incalculable importance in the treatment of many forms of disease, and especially of fevers. Such is the wet sheet.

Of the same order of remedy, although in many respects very different from it, is the Turkish bath, recently introduced into England, and now fairly established throughout the country. In this bath, the hydropathic procedure has received a most important auxiliary in the treatment of many forms of disease, but in an especial manner of the kind more particularly under consideration at present, such as gout, rheumatism, bronchitis, and other complaints of an inflammatory or febrile character. The same end of diaphoresis, or sweating, is secured, although not so efficiently, by means of the vapor bath as used by the Russians, and by hot air as generated by the spirit-lamp. The latter has the advantage of being less expensive, and the bather not being required to breathe the heated air, many persons can use it who would be quite unable to respire, without faintness, the highly heated atmosphere of the Turkish bath. In addition to the above, must be mentioned the use of warm fomentations, in the form of flannels wrung out of boiling-water—a kind of application much relied on for subduing local pain proceeding from whatever cause, for relieving congestion, and abating and checking inflammation. So much for the principal hydropathic operations employed to treat acute and inflammatory diseases—processes corresponding in their aims and effects to antiphlogistic, diaphoretic, and sedative drugs.

We have now to speak of the hydropathic agents brought to bear on the second great division of maladies, wherein the object is not to lower, but to elevate, to the standard of health. In the former class of cases, it was stated that water was the agent most prominently brought forward, and it is in such diseases alone that the term "water cure" is at all appropriate. In those we are at present dealing with, water certainly plays an important part, but it is only in its combination with good air, exercise, regulated diet, and nervous repose, that diseases are cured as they are. As an illustration: A cold bath is given in the usual way as a tonic. Its effects are admirable under certain conditions—the first and chief of these being that a good reaction takes place; that the blood, which had been driven by the constringent effects of the cold water from the surface of the body into the inner parts, should return in increased force when the stimulus of cold is withdrawn. But to this end, in all but very strong persons, exercise immediately after the bath is indispensably necessary, and must follow it as a matter of course, or the bath cannot be administered with comfort, or even with safety. As much might be said for the co-operative importance of pure air, of diet, and of nervous repose, all of them, if necessary to the preservation of health, of tenfold importance in the cure of disease. Thus the highly tonic properties of the bath, administered in its various forms, and followed by a due proportion of exercise, more especially in strong bracing air, produce at once a marvelous effect in sharpening the appetite and improving the powers of digestion, so that, if simple and nourishing diet is administered, better blood will be elaborated, and, consequently, every tissue of the body be more highly nourished and invigorated. It is scarcely necessary to say, that, in all cases, this is and must always be a gradual process, for it is evident that the treatment pursued, whether in reference to exercise, diet, or the use of the stimulus of water, must bear an accurate relation to the invalid's strength. Little by little, however, and in most cases much more rapidly than might be imagined, improvement begins to take place. From the great action brought to bear on the skin by means of the different applications of water, the prudent use of the Turkish bath, and the effects of full exercise, a rapid change of the particles of the body takes place—so rapid, that, according to Liebig, "by means of the water-cure treatment, a change of matter is effected in a greater degree in six weeks, than would happen in the ordinary course of nature in three years"—while, at the same time, the effete matter thrown off is replaced by the healthier materials supplied to the economy by an improved quality of blood, itself the result of an improved digestion, and this, again, resulting from the heightened *vis vitæ* which the combined hydropathic agencies have produced. The forms of the bath may of course be varied *ad infinitum*, as well as its power according to the temperature of the water. The baths most in vogue in daily practice are technically denominated the *wash down*, *dripping sheet*, *shallow*, *sitz bath*, and *douche*, together with the *pack*, or *wet sheet* before mentioned; in addition to which there is a catalogue of local applications, too extensive to enumerate. These various appliances of water are capable of producing extraordinary effects on the economy, constituting, as they do, especially when conjoined with exercise, the most powerful tonics, and, at the same time, the most safe and agreeable, that can be brought to bear on the body. It might truly be added that, in the treatment of chronic disease, this same element, water, is capable of becoming, according to the manner and quantity of its use, internally and externally, an alterative, derivative, diuretic, and diaphoretic. It is as a tonic and stimulant, however, that its virtues are most conspicuous, and most called into requisition for the cure of chronic ailments.

From a variety of circumstances, the system of hydropathic medicine has been

greatly misunderstood and misjudged by the general public. For one thing, the name of "water cure," or "hydropathy," adopted by Priessnitz, has been very prejudicial, as leading to the false inference that the one element of water alone constitutes the bone and marrow of the system, playing the part of a panacea for every form of human ailment. Such a notion has never been maintained by the practitioners of scientific hydropathy, and it is matter of regret that some more comprehensive and catholic title, as that of "hygienic medicine," has not long since been adopted. As it is, the prejudice against the system is gradually giving way; it is no longer treated as heresy by the orthodox profession; and many enlightened practitioners are in the habit of sending certain classes of their patients to hydropathic establishments, and even subject themselves to the treatment. In fact, the tendency of ordinary medical practice has of late years been towards the principles on which hydropathy is based. A manifest disposition exists on the part of the more enlightened members of the profession to rely much less on art and much more on nature in the treatment of diseases of every type, but especially those of a chronic character, than was formerly the case; and as the practitioners of scientific hydropathy by no means exclude the use of drugs, when they appear to be necessary, it would seem that a convergence of opinion is really coming about.

Hydropathy, hitherto, has been almost exclusively practiced in large establishments, presided over by competent medical men, and dedicated to a thorough and systematic carrying out of the principles on which the system of cure is founded. There can be no question that this is by far the most complete and satisfactory arrangement when it can be accomplished. But the power of leaving their daily work for the purpose of seeking health, is what falls to the lot of very few; and if the hydropathic treatment were to be absolutely limited to its chosen retreats in the country, and incompatible with the business and work of town-life, it would be shorn of half its utility as a remedy, and be a luxury to which only the rich and disengaged could aspire. But exercise, morning and evening, can usually be had by most persons. The same applies to the systematic and persistent use of the bath, to the regulation of diet, and the observance of early hours. By these means, even without country air and other hygienic adjuncts, no doubt a vast deal might be done both for the cure of disease and the preservation of health. Towards effecting the latter object, at least, no one will deny the immense value of hydropathy. No one, having any practical acquaintance with it, can doubt its influence in the promotion of those habits of temperance, cleanliness, self-denial, and general obedience to the laws of health, which, while they tend so much to the happiness of the individual, go no less to secure the strength and prosperity of nations. To those who would inquire further into the subject, we may recommend the work of Dr. Gully, entitled *The Water-cure in Chronic Disease;* that of Dr. James Wilson, called *Principles and Practice of the Water-cure;* the several works of Dr. Edward Johnson; and Dr. Lane's treatise, *Hydropathy, or Hygienic Medicine.*

HYDROPH'IDÆ, a group of venomous water snakes, of which more than fifty species are known, chiefly inhabitants of the coasts of eastern seas, from India to Australia and New Zealand. In their form and movements they have a strong resemblance to eels. They have a compressed tail, and are rapid and graceful swimmers, frequenting the mouths of rivers, but are said to be incapable of living out of salt water, although nearly related to the hooded snake or *cobra da capello* of India (q.v.). They are exceedingly venomous and are much dreaded by the fishermen, whose nets often gather them. The order OPHIDIA, to which they belong, are not all as well classified as is desirable. See SERPENTS.

HYDROPHI'LIDÆ, a family of coleopterous insects, called water beetles. They are great swimmers, many of the species having oar-shaped legs. Their larvæ are carnivorous, but the fully developed insect feeds on decayed vegetable matter. Some members of the family inhabit salt water. See COLEOPTERA.

HYDROPHO'BIA (derived from *hydōr*, water, and *phŏbos*, fear) is one of the diseases that are produced by animal poisons. A person is bitten by a mad dog or other animal. The wound gradually heals in the ordinary manner. After an uncertain interval, usually ranging from six weeks to eighteen months, which is termed the period of *incubation*, the following symptoms appear: The patient experiences discomfort or pain at the seat of the bite. The cicatrix tingles or feels stiff or numb; sometimes becomes swelled and livid, and occasionally reopens, and discharges a peculiar ichor. The morbid sensations gradually extend from the original seat of injury towards the trunk. This period is termed the stage of *recrudescence*. Within a few hours, or, at longest, a very few days after the exhibition of this local irritation, during which time the patient has a sense of general discomfort and illness, the specific constitutional symptoms begin to manifest themselves; he complains of pain and stiffness about the neck and throat, finds himself unable to swallow fluids, and every attempt to do so—often even the sight or the sound of fluids—brings on a terrible paroxysm of choking and sobbing; and this continues for two or three days, till the patient dies from pure exhaustion. The passage of a gust of wind across the face, or the waving of a mirror before the eyes, is often sufficient to excite these paroxysms. The mental condition in the last stage of this disease varies; the patient may be calm and tranquil; generally he

is irritable and apprehensive, and suspicious; and in most cases, a certain degree of delirium, or even mania, is associated with the irritability. Death most commonly takes place on the second or third day after the commencement of the specific symptoms.

Some medical writers have maintained that hydrophobia may occasionally be spontaneously developed in man, as is undoubtedly the case occasionally in the lower animals (the dog and wolf, for example); but even if this ever occurs, the instances are so extremely rare as not to affect the general statement, that in man the disease is the result of an animal poison, which is most commonly communicated by the bite of the dog, but which has also been produced by the bite of the wolf, the jackal, the raccoon, and the cat. The poisonous saliva is perfectly innocuous when applied to the unbroken skin; to produce its effects, there must be some abrasion of the cuticle; but according to the late Mr. Youatt, it may enter the system by mere contact with mucous membranes.

The disease is said to have been caused by the mere *scratch* of a cat; but as both cats and dogs frequently apply their paws to their mouths, the poisonous saliva may be introduced in this way by the claws.

There has been much discussion as to what becomes of the poison. Is it immediately taken into the system generally, or does it remain imprisoned in the wound or cicatrix for a time? In the latter case, we might successfully remove the poison any time between the infliction of the bite and the period of recrudescence; and that the poison is thus locally retained seems more than probable from the fact that at this period morbid phenomena of various kinds exhibit themselves at the seat of the wound, and that these phenomena are speedily followed by the characteristic symptoms of the disease.

Little need be said of the treatment of hydrophobia, for there is no well-authenticated case of recovery on record. The most distressing symptoms may, however, be alleviated by chloroform, opiates, the hot-air bath, etc. But although the disease cannot be cured, its development may be prevented by the early and complete excision of the bitten part, provided the situation of the bite allows of the free use of the knife. "If," says Dr. Watson, "the injury be so deep or extensive, or so situated that you cannot remove the whole surface of the wound, cut away what you can; then wash the wound thoroughly and for some hours together, by means of a stream of warm water, which may be poured from a tea-kettle; place an exhausted cupping-glass from time to time over the exposed wound; and finally apply to every point of it a pencil of lunar caustic. If you cannot bring the solid caustic into contact with every part, you had better make use of some liquid escharotic; strong nitric acid, for example." Early excision is the only sure preventive, but if, for any reason, the operation has been omitted in the first instance, it is advisable, for the reasons already given regarding the probable latency of the poison, to cut out the wound at any period before symptoms of recrudescence appear. The reason why many neglect to have immediate recourse to excision probably is, that hydrophobia by no means follows, as a matter of certainty, the bite of a rabid animal. John Hunter states that he knew an instance in which, of twenty-one persons bitten by a mad dog, one alone was infected. On the other hand, we have evidence that of one hundred and fourteen persons who were bitten by rabid wolves, sixty-seven, or more than one half, were victims to this disease. Although we have no very trustworthy evidence on a large scale, there is no doubt that the majority of persons who are bitten by a mad dog do escape the disease, even without taking any precaution. In many of these cases, the virus is probably removed by the teeth passing through the clothes.

The nature of the disease in the dog or other animal whose bite causes hydrophobia, is considered under RABIES.

HYDROPHYLLA'CEÆ, a natural order of exogenous plants, containing about 80 known species, natives chiefly of the colder parts of America. None of them are of importance for any use to which they are applied, although *hydrophyllum canadense* has been reputed in North America a remedy for snake bites, and the leaves of *H. virginicum*, or Shawanese salad, are eaten by the Indians, both raw and boiled; but some of them are favorite ornaments of our flower-borders, particularly different species of *nemophila*. The order includes some small trees and bushes as well as herbaceous plants. They are often hispid, like the *boraginaceæ*.

HYDROSTAT'ICS treats of the equilibrium of liquids, and of their pressures on the walls of vessels containing them; the science depends on the way in which the molecules of a liquid form a mass under the action of gravity and molecular attraction, the latter of which is so modified in liquids as to give them their state of liquidity. While the particles of a liquid cohere, they are free to slide upon one another without the least apparent friction; and it is this perfect *mobility* that gives them the mechanical properties considered in hydrostatics.

The fundamental property may be thus stated: WHEN A PRESSURE IS EXERTED ON ANY PART OF THE SURFACE OF A LIQUID, THAT PRESSURE IS TRANSMITTED UNDIMINISHED TO ALL PARTS OF THE MASS, AND IN ALL DIRECTIONS. Most of the other propositions of hydrostatics are only different forms or direct consequences of this truth. This is a physical axiom, but its truth may be experimentally proved. Suppose a close

box B filled with water, and having a tube *a* inserted into the upper cover, of an inch in area, and with a plug or piston fitting into it. If the piston *a* is now pressed down upon the water with a force equal to a pound-weight, the water, being unable to escape, will react upon the piston with the same force; but it obviously will not press more against *a* than against any other part of the box, therefore every square inch of the interior surface of the box is pressed outward with the force of a pound. If, then, there is another tube inserted in any part of the box with a plug of the same area, as at *b*, it will require a force of a pound to keep this plug in its place. (We leave out of account at present the pressure upon *b* arising from the *weight* of the water in the box above it, and consider only the pressure propagated by the forcing down of the plug *a*.) However many plugs of the same size there were, each would be pressed out with the same force of a pound; and if there were a large plug of four times the area, as at *c*, it would be pressed out with a force of 4 lbs. We have only, then, to enlarge the area of the piston *c* to obtain any multiplication of the force exerted at *a*. If the area of *c* is 1000 in., that of *a* being 1 in., a pressure of 1 lb. on *a* becomes a pressure of 1000 lbs. on *c*; and if we make the pressure on *a* 1 ton, that on *c* will be 1000 tons. This seemingly wonderful multiplication of power has received the name of the *hydrostatic paradox*. It is, however, nothing more than what takes place in the lever, when 1 lb. on the long arm is made to balance 100 lbs. on the short arm.

If the pressure we have supposed exerted on the piston *a* arose from a pound of water poured into the tube above it, it would continue the same though the piston were removed. The pound of water in the tube is then pressing with its whole weight on every square inch of the inner surface of the box—downwards, sidewise, and upwards. The apparatus called the *hydrostatic bellows* acts on this principle (see Fig. 2). It consists of two stout circular boards connected together by leather in the manner of a bellows, B. The tube A is connected with the interior; and a person standing on the upper

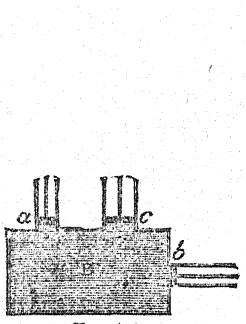


Fig. 1.

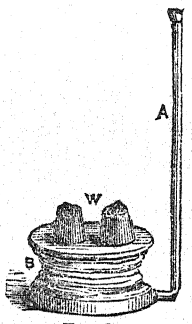

Fig. 2.

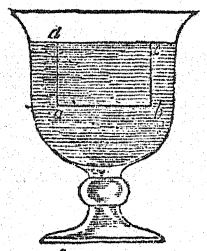

Fig. 3.

board, and pouring water into the tube; may lift himself up. If the area of the upper board is 1000 times that of the tube, an ounce of water in the tube will support 1000 ounces at W. It is on the same principle that the hydraulic press (q.v.) depends.

1. *Equilibrium of Liquids.*—After this explanation of the fundamental properties of liquids, it may be enough to state the two conditions of fluid equilibrium which directly flow from it. (1.) Every molecule of the liquid must be solicited by equal and contrary pressures in every direction. This is a corollary from liquid mobility. (2.) The upper molecules of a liquid, which are free, must form a surface perpendicular to the impressed force. The truth of this will sufficiently appear from the proof that the surface of a liquid at rest under gravity must be what is called horizontal. It can be shown to be a consequence of the primary property of "pressing equally in all directions." For let *da* and *cb* be vertical lines, or lines in the direction of gravity; and *ab* a plane at right angles to that direction, or horizontal. A particle of the liquid at *a* is pressed by the column of particles above it from *a* to *d;* and the like is the case at *b*. Now, since the liquid is at rest, these pressures must be equal; for if the pressure at *b*, for instance, were greater than at *a*, there would be a flow of the water from *a* towards *b*. It follows that the line *ad* is equal to *be*, and hence that *dc* is parallel to *ab*, and therefore horizontal. The same might be proved of any two points in the surface; therefore the whole is in the same horizontal plane.

2. *Pressure of Liquids on Surfaces.*—The general proposition on this point may be stated thus: *The pressure of a liquid on any surface immersed in it, is equal to the weight of a column of the liquid whose base is the surface pressed, and whose height is the perpendicular depth of the center of gravity of the surface below the surface of the liquid.* See article Center of Pressure. The pressure thus exerted is independent of the shape or size of the vessel or cavity containing the liquid.

3. *Buoyancy and Flotation.*—As a consequence of the proposition regarding the pressure of liquids on surfaces, it can be shown that when a solid body is immersed in a liquid, it loses as much weight at that of an equal bulk of the liquid weighs. It follows that, if a cubic foot of the liquid and of the solid have equal weights, the solid will lose all its weight, or will remain in the liquid wherever it is put; if a cubic foot of the

liquid weigh more than one of the solid, the solid will not only lose all its weight, but will rise up, and that with a force equal to the difference; if a cubic foot of the liquid weigh less than one of the solid, the solid will lose weight, but will sink.

When a solid swims, or rises and *floats* on the surface of a liquid, the next problem of hydrostatics is to determine how much of it will be below the surface. We have already seen that any solid in a liquid is pressed upward with a force equal to the weight of the water whose room it occupies. Now, a floating body must be pressed up with a force equal to its own weight, otherwise it would sink lower; hence, *a floating body displaces its own weight of the liquid.* A solid, as AB in Fig. 4, sinks until the space occupied by the part B immersed would contain an amount of water equal in weight to the whole solid AB.

FIG. 4.

As the buoyancy of a body thus depends on the relation between its weight and the weight of an equal bulk of the liquid, the same body will be more or less buoyant, according to the density of the liquid in which it is immersed. A piece of wood that sinks a foot in water, will sink barely an inch in mercury. Mercury buoys up even iron. Also a body which would sink of itself, is buoyed up by attaching to it a lighter body; the bulk is thus increased without proportionally increasing the weight. This is the principle of life-preservers of all kinds. The heaviest substances may be made to float by shaping them so as to make them displace more than their own weight of water. A flat plate of iron sinks; the same plate, made concave like a cup or boat, floats. It may be noted that the buoyant property of liquids is independent of their depth or expanse, if there be only enough to surround the object. A few pounds of water might be made to bear up a body of a ton weight; a ship floats as high in a small dock as in the ocean.

4. *Stability of Floating Bodies.*—Conceive *abd* (Fig. 5) to be a portion of a liquid turned solid, but unchanged in bulk; it will evidently remain at rest, as if it were still liquid. Its weight may be represented by the force *cg*, acting on its center of gravity *c*; but that force is balanced by the upward pressure of the water on the different parts of the under surface; therefore, the resultant of all these elementary pressures must be a force, *cs*, exactly equal and opposite to *cg*, and acting on the same point *c*, for if it acted on any other point, the body would not be at rest. Now, whatever other body of the same size and shape we suppose substituted for the mass of solid water *abd*, the supporting pressure or buoyancy of the water around it must be the same; hence we conclude that *when a body is immersed in a liquid, the buoyant pressure is a force equal to the weight of the liquid displaced, and having its point of application in the center of gravity of the space from which the liquid is displaced.* This point may be called the *center of buoyancy.*

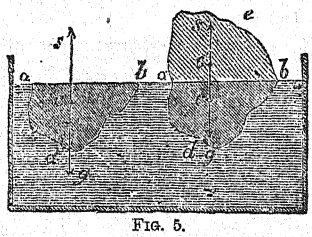

FIG. 5.

We may suppose that the space *abd* is occupied by the immersed part of a floating body *aebd* (Fig. 5). The supporting force, *cb*, is still the same as in the former case, and acts at *c*, the center of gravity of the displaced water; the weight of the body must also be the same; but its point of application is now *c'*, the center of gravity of the whole body. When the body is floating at rest or in a state of equilibrium, this point must evidently be in the same vertical line with *c*; for if the two forces were in the position of *cs*, *c'g* (Fig. 6), they would tend to make the body roll over. The line passing through the center of gravity of a floating body and the center of gravity of the displaced water, is called the *axis of flotation.*

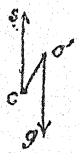

FIG. 6.

The equilibrium of a floating body is said to be *stable*, when, on suffering a slight displacement, it tends to regain its original position. The conditions of stability will be understood from the accompanying figures. Fig. 7 represents a body floating in equilibrium, G being its center of gravity, B its center of buoyancy, and AGB the axis of flotation, which is of course vertical. In Fig. 8 the same body is represented as pushed or drawn slightly from the perpendicular. The shape of the immersed portion being now altered, the center of buoyancy is no longer in the axis of figure, but to one side, as at B. Now, it is evident that if the line of direction of the upward pressure—that is, a vertical line through B—meets the axis above the center of gravity, as at M, the tendency of the two forces is to bring the axis into its original position, and in that case the equilibrium of the body is stable. But if BM meet the axis below G, the tendency is to bring the axis further and further from the vertical, until the body get into some new position of equilibrium. There is still another case; the

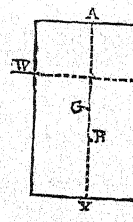

FIG. 7.

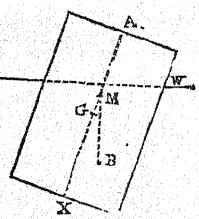

FIG. 8.

line of support or buoyancy may meet the axis in G, and then the two forces counteract one another, and the body remains in any position in which it is put; this is called *indifferent* equilibrium. In a floating cylinder of wood, for instance, B is always right under G, in whatever way the cylinder is turned. When the angles through which a floating body is made to roll are small, the point M is nearly constant. It is called the *metacenter;* and its position may be calculated for a body of given weight and dimensions. In the construction and lading of ships, it is an object to have the center of gravity as low as possible, in order that it may be always below the metacenter. With this view, heavy materials, in the shape of ballast, are placed in the bottom, and the heaviest portions of the cargo are stowed low in the hold. See SPECIFIC GRAVITY and AREOMETER.

HYDROSULPHU'RIC ACID (HS), known also as *sulphureted hydrogen, sulphydric acid,* and *hydrothionic acid,* is a natural gaseous constituent of many mineral waters, as, for example, those of Aix-la-Chapelle in Germany, Barèges in France, Abano in Italy, and Harrogate in England, and is evolved from fumaroles and volcanoes. It is formed spontaneously wherever sulphurous organic matters are undergoing putrefaction, as, for instance, in stagnant sewers and cess-pools, and in waters charged with organic matter and sulphates, especially sulphate of lime.

There are several ways of preparing this gas, which is very extensively used in laboratory operations. The following is that which is most commonly employed. Sulphide (the old sulphuret) of iron, in small fragments, is placed in a bottle, and dilute sulphuric acid is added. Water is decomposed, its hydrogen combining with the sulphur of the sulphide to form hydrosulphuric acid, which escapes as a gas, while its oxygen enters into combination with the iron, forming oxide of iron (FeO), which unites with the sulphuric acid to form the ordinary protosulphate of iron or green vitriol, which remains in solution. The reaction is expressed by the equation:

Sulphide of Iron.		Sulphuric Acid.		Hydrosulphuric Acid.		Sulphate of Iron.
FeS	+	HO,SO_3	=	HS	+	FeO,SO_3

Hydrosulphuric acid is a colorless gas of a strong and very nauseous odor, resembling that of rotten eggs. It consists of two volumes of hydrogen and one volume of sulphur vapor condensed into two volumes, which form its combining measure. It is about seventeen times heavier than hydrogen. By pressure it is liquefied, and by the additional application of cold, it may be obtained in the solid form (see GASES). Water dissolves, at 59°, 3.23 volumes of this gas, but the solution soon becomes milky when exposed to the air, in consequence of the oxygen of the air combining with the hydrogen of the gas, and sulphur being precipitated. It is highly combustible, and burns with a pale blue flame, producing water and sulphurous acid, and, generally, a deposit of sulphur. It has a weak acid reaction, and forms one of the hydracids. Although a feeble acid, it combines readily with bases.

Its use as a reagent is dependent on the fact, that many of the sulphides which it forms with metallic oxides are insoluble in water, and are thrown down from solutions as precipitates with characteristic colors. Thus the gas, or a watery solution of it, gives an orange precipitate with the compounds of antimony, while with those of arsenic it gives a yellow—with those of lead and of silver, a black—and with those of zinc, a white precipitate.

The air of a room slightly impregnated with this gas may be breathed with impunity, but a small quantity of the undiluted gas inspired produces faintness, and its respiration, in a very moderate proportion, was found by Thenard to prove fatal—birds perishing in air which contained $\frac{1}{1500}$th, and a dog in air containing $\frac{1}{800}$th part of this gas. Its poisonous effects are best counteracted by the inhalation of very diluted chlorine gas, which may be readily obtained from a little chloride of lime placed in the folds of a napkin moistened with vinegar.

A very minute trace of this gas may be detected by placing a piece of paper, moistened with a strong solution of sugar of lead, over the vessel or aperture—as, for instance, over an opening in a drain—from which we think it is escaping. If it be present, a more or less black—often only a brown—tint is developed after a few minutes, in consequence of the formation of sulphide of lead.

HYDROTHO'RAX (derived from *hydōr*, water, and *thorax*, the chest) is the term applied to dropsical collections in the pleura (q.v.), a closed serous sac enveloping the lung on either side. When it exists to any extent, the pressure which it exerts on the lungs impedes the passage of the blood through them, and occasions difficulty of breathing, lividity of countenance, etc.; and more or less dropsy in the face, ankles, etc., soon appears. The physical signs by which the disease can be detected are too purely professional for these pages.

The causes of hydrothorax are various. It may depend upon inflammation of the secreting membrane, or it may be a consequence of organic disease of the heart or lungs. With regard to treatment when the disease seems to depend upon inflammation of the pleura, great advantage may often be derived from occasional cupping and repeated blistering. The most popular internal remedy is a combination of squill and

either calomel or blue pill, which must be continued till slight symptoms of salivation manifest themselves.

HYDROZO'A. See ZOOPHYTES.

HYE'NA, a genus of digitigrade carnivorous quadrupeds, included in the genus *canis* by Linnæus, and by some naturalists referred to the family *canidæ*, but now more generally to *viverridæ*, whilst the dentition connects it even with *felidæ*. Hyenas have six incisors and two canine teeth in each jaw, five molars on each side in the upper jaw, and four in the under. They seize an object with so firm a hold, that, among the Arabs, they are proverbial for obstinacy. The vertebræ of the neck sometimes become anchlosed in old hyenas. The hind-quarters are lower and weaker than the fore-quarters of the body, so that hyenas move with a shambling gait. The body is covered with rather long coarse hair, forming a mane along the neck and back. The feet have each four toes. The claws are strong, fit for digging, and not retractile. The tail is rather short. Beneath the anus is a deep glandular pouch, contributing much to the offensive odor by which hyenas are characterized. Hyenas eat carrion, as well as newly killed prey, and are of much use, like vultures, as scavengers, clearing away the last remnants of carcasses that, if left to rot, would greatly pollute the air. They sometimes attack cattle, especially if they flee, but rarely man, though they sometimes seize children. During the day they hide themselves in caves, old rock tombs, ruined edifices, etc.; by night, they roam singly or in packs in quest of prey. They prowl about towns and villages, and often dig up corpses that have not been very deeply buried. This, together with their aspect and manners, has caused them to be generally regarded with horror, and very exaggerated accounts of their fierceness have been prevalent. Instead of being untamable, as was long the popular belief, they are capable of being very completely tamed, and show an attachment to man similar to that of the dog; they have even been used as watch-dogs. Hyenas are found only in Africa and the s. of Asia, not extending to the farthest s. of the latter continent.—The STRIPED HYENA (*H. vulgaris* or *striata*) is found both in Asia and Africa, and there are several varieties considerably different in size, color, etc. The smallest hyenas are of the size of a large dog.—The SPOTTED HYENA (*H. crocuta*) inhabits s. Africa. It is rather smaller than the largest varieties of the striped hyenas, but is more fierce and dangerous. It is called TIGER-WOLF by the colonists of the cape of Good Hope. Besides its ordinary howling, which it emits very freely in its nocturnal roamings, this hyena often indulges in an expression of gratification or of some passion, resembling hysterical laughter, whence it has acquired the name of the LAUGHING HYENA. The general color is ochry gray, with thinly scattered small round brown spots, and sooty muzzle and feet.—The WOOLLY HYENA (*H. villosa*) is a smaller s. African species.

In consequence of the bones which hyenas eat, their dung forms solid yellowish-white balls, of compact earthy fracture, the *album græcum* of the old materia medica.

HYÈRES, or HIÈRES, a small t. of France, in the department of Var, is situated 3 m. from the Mediterranean, and 8 m. e. of Toulon. It is celebrated for the beauty of the situation and the mildness of the climate, and is therefore much resorted to by foreigners suffering from chest or nervous complaints. Pop. '76, 6,797. Near the coast lie the Iles d'Hières, called by the ancients the Stœchades, which, with the exception of the military garrisons of a few forts, are uninhabited. Here the heat of the climate is tempered by the sea-breezes, and the season seems an eternal spring.

HYGE'IA—in the classical mythology, the goddess of health—the daughter of Æsculapius. She was worshiped at Athens, Corinth, Argos, and other important cities, and in works of art is usually represented as a blooming virgin, with a snake, the symbol of health, which drinks from a cup held in her hand. HYGEIA is the name of one of the newly discovered planetoids (q.v.).

HYGIENE (HEALTH, *ante*), the science of health, also called sanitary science. The word is originally derived from Hygeia, the goddess of health, a daughter of Æsculapius. Hygiene includes attention to diet, to exercise, to mental and physical habits, as well as to clothing, climate, state of the weather, condition of dwellings and of the streets and sewers of the town, or of the surface of the country. It is a subject which has received various degrees of attention in all ages, but as a science it is of modern date. However much attention may have been given to the rules and practice of exercise, and to bathing and habits of cleanliness by ancient nations, and however much knowledge they may have had of the advantages to health which were derived from their games, their baths and other observances, their want of knowledge of many of the causes of disease was a barrier to scientific knowledge. An individual may be ever so particular in the care of his person, but if he habitually breathe an atmosphere loaded with malaria, he will almost certainly at some time be prostrated with some form of fever. If science has never analyzed for him the effluvia of the cess-pool or the pile of putrescent matter lying near his dwelling he cannot have any other knowledge which will lead him to avoid the deleterious influences of their presence. Neither can he form rules of eating and drinking, or even of exercise or bathing, which will not in some degree violate the laws of health, unless he has an extensive knowledge of the principles of physiology. Now, physiology is a modern science, and although it enables us to avoid many dangers,

it is still so far in its infancy as to allow us at times to adopt erroneous habits, and our knowledge of malaria and of its propagation does not always tell us how to employ the most efficient measures against it. How then could the ancients protect themselves against the ravages of the plagues and pestilences which periodically carried them off by hundreds of thousands? And it must be confessed that modern nations, until within a very recent period, even within the lives of persons now living, have known but little more than the ancients of any practical preventives against the ravages of diseases; and moreover, it must with shame be confessed that at the present time, and in some of the most enlightened and luxurious cities, whose municipal authorities have only to ask to receive the most scientific advice from the medical profession and the aid of the most accomplished engineers, methods for riddance of pestilential matter are employed but little better than those which would be adopted by barbarians.

Omitting the considerations of the sanitary measures pursued by the Assyrians, Egyptians, Greeks, and Romans, some of which are recorded in architectural monuments preserved to this day, we find that in England in the time of Edward II., among other ordinances of a sanitary nature, there was one forbidding the sale of muzzled swine's flesh; and in the reign of Richard II. one to prevent the pollution of rivers, and subsequently, including the reign of Elizabeth, ordinances for the inspection and cleansing of sewers, and the prevention of overcrowding in tenements. But notwithstanding the attention thus early given to the subject of the pollution of rivers, some of the water that is supplied to the city of London to-day receives pollution from the sewage of towns. Much, however, has been done by men of science to point out the manner of effecting sanitary reforms, and it may reasonably be hoped that the day is not distant when as a rule municipal authorities will be compelled by process of law, or by public sentiment, if not impelled from patriotic or public spirited motives, to employ the best methods of introducing pure and non-malarialized water into our cities, and also to clean the streets and dispose of the offal and refuse in such manner as not to sacrifice human life, or even to shock public decency or discourage private enterprise.

Hygiene may be variously classified, according to its relations, and the objects in view. There is the hygiene of the individual, of the family, and of the municipality or state; which may be denominated personal, domestic, and public hygiene. Personal hygiene has little to consider beyond questions of diet, cleanliness of person, habits of thought and study, and of morals and locality of residence. Domestic hygiene regards the condition of the whole household, the apportionment of sleeping apartments to different members, the general regulation of meals and the preparation of food, and is brought into more immediate relations with public hygiene, as the householder will often need to have intercourse with the public authorities. Public hygiene has the consideration of measures for the laying out of a city, for the disposal of its refuse, for the supply of water, and the occasional enforcement of quarantine regulations. In a more enlightened sense it must also have regard for the education of the inhabitants in such a manner as will dispose them to cleanly and thrifty habits. Hygiene may be also divided into mental and physical. The former will necessarily include many questions that belong to the latter, for the healthy action of the mind depends to a great extent upon the health of the body. A sufficient amount of sleep ought to be taken to refresh the powers of the mind as well as those of the body, and that sleep ought not to be much disturbed by dreams. It is a matter of common experience that retiring at night with too full a stomach—and with some persons with any food in the stomach—is provocative of disturbing dreams. The thoughts should be calm, and mental exercise, as well as physical, should be regularly taken. Of course there are those whose occupation demands varied, sometimes excessive exertions, and who must be "a law unto themselves." No rules of mental hygiene are possible with them, except that they shall keep the blade of the intellect as keen and as bright as possible by a fair diet, what exercise they can find time to enjoy, and be always ready for an intellectual encounter. There are lawyers and other professional men, journalists, physicians, and a few public officers whose duties are so thoroughly wound up in the progress and success of causes and enterprises, in questions of life and death, and the loss or the rescuing of fortunes, that there is scarcely such a word as *rest* with any practical import to them. But the great time for practically applying the laws of mental hygiene is during the years of childhood and youth, before the struggles of life commence. The method of teaching the child should be of the simplest as well as of the most comprehensive character, and the periods should be frequent during which its mind is completely taken away from all serious study, and allowed to come to a perfectly natural and passive condition by mirthful and affectionate enjoyment. Let the schoolrooms to which youth are sent be commodious and well ventilated, and after these advantages are secured let them not be thrown away by overcrowding. It is questionable whether the bringing together of over one thousand, or even that number, of children in one building, even though a large one, is not in violation of sanitary principles. Too many studies should not be required, so that hours which should be given to recreation or sleep will not be occupied, as is now too often the case, with laborious efforts of study, which often do little more than produce a disturbed and unrefreshing sleep, and pervert or destroy the appetite for wholesome food. As to moral hygiene, which is a part of mental, it is necessary to say only that the strict observance of those laws which are

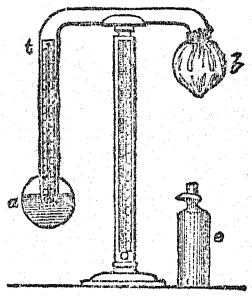
inculcated by Christianity and sought to be enforced by the civil authorities of all enlightened nations, will be conducive not only to soundness of the whole mind, but also to soundness of the whole body.

Physical hygiene presents itself in various aspects, embracing exercise, diet, occupation, etc. Exercise is an important element of hygiene. See EXERCISE, GYMNASTICS, *ante*. For the hygiene of diet, see DIET, *ante*. By the hygiene of occupation or employment is meant the hygienic influence of different employments upon the individual. It is evident that the occupation of a lawyer or journalist or physician has vastly different hygienic relations from that of a shoemaker or carpenter. It is evident that a carpenter will need but little more exercise than is given him by his occupation; but his diet, and his time and manner of sleeping, and his habits of cleanliness and bathing, will have considerable importance. It is hardly necessary to say that he should have a generous diet, should occupy an airy and well-ventilated chamber for sleeping, and that his food shou'd usually be different from that of the shoemaker, lawyer, or doctor. It may be said in general that active laboring men, like carpenters, wheelwrights, and farmers, may partake of food which takes a considerable time to digest, with more advantage than sedentary men can. Pork and corn-cake or bread is a nutritious and sustaining diet to an active laborer, but should not form the habitual diet of a sedentary person. But the influence which the occupation of a person may have upon his health is a hygienic question which can only be hinted at in a brief treatise. The rules of hygiene are subject to change according to circumstances. That which is beneficial to one person is often injurious to another, and nothing but the application of the broadest common sense in the most catholic spirit can be expected to apply to questions as to what any person ought to eat, to drink, or as to how many miles he or she ought to walk every day. In conclusion, it may be remarked of public hygiene that it can only be regulated by the enforcement of sanitary laws; and that to be efficient, especially in cities, they need to have reference to many things. One of the most important questions of public hygiene is the cleaning of streets and matters connected therewith. Filthy streets are productive of disease not only by the generation of poisonous gases, but also the dust which results from the long-continued trituration of excrementitious and decaying substances is extremely injurious to the mucous membrane of the air passages, and productive of contamination to blood and tissue. The habit of casting the sweepings of houses and stores, upon the sidewalks, especially during the hours in which pedestrians are passing, which is so prevalent in most of our cities, is a greater evil than many suppose. The dust of these places is often of the most objectionable character, containing the germs of contagion, and there is no doubt that many filthy diseases are propagated in this manner. It is impossible to see how such abuses can be remedied, except by municipal regulation.

Public conveyances are frequent causes of disease from various sources. The dust which is allowed to collect in street cars, and also ordinary steam railway cars, is of itself a frequent cause of diseases of the air passages; but compared to the evils which result from overcrowding and bad ventilation, it is of minor importance. The overcrowding which is deliberately practiced on some of the street railroads, coupled with the draughts of cold air from windows opened regardless of comfort, is undoubtedly a considerable factor in the death-rate of our large cities. Pneumonia, pleurisy, bronchitis, and laryngitis are frequent results of street-car exposure. But one of their greatest evils, and one not yet sufficiently recognized by the public, although well known to the medical profession, is the want of attention paid to the smoothness of the track and the springs of the cars. This is commonly regarded as a matter of comfort, but this is its least important aspect. There is a disease recognized in legal medicine called railroad disease. It is a nervous affection, caused by the continuous vibration of the cars. This vibration cannot be entirely avoided on rapid trains, but on some roads is so nearly so that little mischief probably results from this cause. On street cars undue jarring should not be permitted. When they are properly supplied with springs, and the seats cushioned, all injurious vibrations will be avoided, even when the track is not perfectly smooth. A delicate lady is often seriously injured by riding in a car on a bare wooden seat, without a cushion to relieve the jar resulting from the imperfect springs, and physicians are constantly meeting with patients whose diseases are directly traceable to this cause. Several years ago, when the street cars, which were then cushioned, became so filthy as to be known agents of contamination, the abandonment of cushions was popularly hailed as a relief. It was, however, only a partial relief, from filthiness; it has been injurious in another direction, but there is no reason why the seats of all public conveyances, which are paid, as a rule, in proportion to the amount of wear entailed by travel, cannot be comfortably cushioned and kept clean. Hygiene has its thousand relations to all the habits and conditions of life, and although many of them lie within the limits of private life and cannot be subjected to legal interference, gross violations of sanitary laws ought not to be permitted in public establishments. See WARMING AND VENTILATION.

HYGROM'ETER (Gr. *hygros*, moist, *metron*, measure), an instrument for measuring the quantity of moisture in the atmosphere. The earlier forms of hygrometer depended upon the property possessed by some substances of readily absorbing moisture from the air, and being thereby changed in dimensions or in weight. Of this kind was the hair

hygrometer of Saussure, in which a hair, which expands and contracts in length according as the air is more or less moist, was made to move an index; a similar instrument was the whalebone hygrometer of Deluc; but as other causes as well as moisture affect such instruments, they afford no accurate indications. The most perfect hygrometer, theoretically, is that of J. F. Daniell (q.v.). It consists of two bulbs connected by a bent tube, as represented in the figure, and inclosing a thermometer, together with some ether and vapor of ether, the air having been expelled. The bulb, *b*, is covered with muslin, and *a* is either blackened or coated with metal. The observer's hand is placed for a short time on *b*, to drive the ether into *a*, leaving *b* and the tube filled with vapor of ether. A little ether is then dropped from a flask, of the form *c*, on the muslin-covered bulb; evaporation instantly takes place, and produces a cooling of *b*, which condenses the vapor inside; a fresh evaporation from *a* fills the vacuum, which is again condensed by dropping ether on *b*, and the process is repeated till the temperature of *a* is so reduced by successive evaporations (see EVAPORATION), that *dew* begins to be formed on the outside of the bulb. At the instant this occurs, the height of the mercury in the two thermometers is accurately noted, the one giving the dew-point temperature, and the other the temperature of the air. The actual quantity of moisture contained in a cubic foot of air can now be readily found from the following empirical formula: weight of moisture in grains $= \frac{5656.2}{448 + t} \times p$; where t is the temperature of the air at the time of observation, and p (found from tables) the elasticity of vapor at the temperature of the dew-point. The evident defects of this instrument are, first, its rapidity of operation, so that no time is allowed for the glass, ether, and thermometer to come to the same temperature, and, in consequence, the dew-point is given higher than it actually is; secondly, its costliness, owing to the great consumption of ether; and, thirdly, its uselessness in tropical countries, owing to the difficulty of preserving the ether in a fluid state. Daniell's hygrometer was used at the royal observatory, Greenwich, from 1840—the commencement of meteorological observations—till 1847, when it was superseded by the more convenient instrument, the WET AND DRY BULB THERMOMETERS. This instrument consists of two ordinary thermometers—one has its bulb bare, and thus shows the temperature of the air; the other has its bulb covered with muslin, which is kept wet by a cotton wick dipping into water. The evaporation from the muslin, and consequent cooling of the bulb, being in proportion to the dryness of the air, the difference between the readings of the two thermometers is greatest when the air is driest, and zero when it is completely saturated. The readings of the thermometers being taken, the elastic force of vapor at the dew-point is calculated by the formula of Dr. Apjohn (*Proceedings of the Royal Irish Acad.*, 1840):



$$(1)\ F = f - \frac{d}{88} \cdot \frac{h}{30};\quad (2)\ F = f - \frac{d}{96} \cdot \frac{h}{30};$$

the first formula to be used when the wet thermometer is above, and the second when it is below, the freezing-point (32°). In these formulæ, F is the elastic force of vapor at the dew-point, which has been determined for different temperatures by Regnault from carefully conducted experiments; *f*, the elastic force at the temperature of evaporation (or reading of wet bulb); *d*, the difference between the dry and wet bulbs; and *h*, the height of the barometer. From this the quantity of moisture in a cubic foot of air, etc. can be found as before. To dispense with these troublesome calculations, the *Hygrometric Tables* of Mr. Glaisher may be used.

HYKSHOS, the name of an Egyptian dynasty, generally known as the Shepherd Kings, derived from *hyk*, a ruler, and *shos*, a shepherd; or, according to another version, from *hyk*, a captive, and *shos*, a shepherd. According to Josephus and Africanus, they consisted of six or eight kings, named (1), Salatis, Silitis, or Saites, who reigned 19 or 15 years; (2), Beon, Banon, or Bnon, who reigned 43 or 44; (3), Apachnas, Apachnan, or Pachnas, who reigned 36 or 61 years; (4), Apophis, Aphosis, who reigned 61; (5), Anas, or Anan, who reigned 50; (6), Archles, who reigned 49; (7), Assis, or Asseth, who reigned 49 years and 2 months; and (8), Apobis, who reigned 61 years. The greatest discrepancy exists in the names and their arrangement, and as to the total number of years of the dynasty. Manetho, according to Josephus, states that they reigned 511 years, but the total of the reigns he cites amounts to only 259 years 10 months; while Africanus makes their duration 284 years, and Eusebius 103. Africanus makes the shepherds consist of the 15th, 16th, and 17th dynasties, and to have ruled 953 years, but only gives the names and reigns of one, which he calls the 15th; while Eusebius makes them more correctly the 17th dynasty. They are stated in the Egyptian annals to have been a race of conquerors sprung from the east, who, under Salatis, their first king, took Memphis, and rendered tributary the whole of Egypt, and fortified the city of Avaris, on the e. of the Bubastite arm of the Nile, where he maintained a garrison of

240,000 soldiers. Their oppression, however, drove the Egyptians to revolt, and under Taakan, the predecessor of Aahmes or Amasis I. of the 18th dynasty, a religious quarrel about the temples of Ra or the sun, and of Set, the god of the Hykshos, seems to have commenced, when a long war broke out, which ended under Aahmes, with the siege of Avaris and a king who is called Misphragmuthosis, supposed to be a Thothmes, finally drove them out. The monument of an officer, named Aahmes-Penneben, at El Kab, recounts this siege and his exploits. Finally, according to Manetho, they departed under treaty. The great interest attaching to the Hykshos is that they were confounded with the Hebrews, or supposed to be the monarchs under whom Joseph entered Egypt, by the old ecclesiastical writers. In the monuments and the papyrus of Turin in which portions of their names occur in the list of the kings, they bear the full titles of monarchs, although the papyri state that there were no kings in Egypt at the time, and that Taakan was only himself a *hek*, or prince of the south. The Hykshos, on a contemporary inscription remaining at El Kab, are called *mena*, or shepherds. The Hykshos were by no means the devastating conquerors described by the historian. They entered Egypt, it appears from the monuments, about the 14th Egyptian dynasty, and were content with inscribing their names and titles on the monuments of their predecessors, the name of Appapus having been found on a colossus of Sebakhetp III. of the 13th dynasty, and on that of a king of the 14th dynasty at San. Traces of that of Saites or Salatis have been also found at Tel-Mokdam or Cynopolis. The greatest divergence of opinion has prevailed amongst authors as to their race and origin. Josephus calls them Hebrews or Arabs; the Syncellus, Phenician shepherds. They have also been supposed to be Idumeans, Ishmaelites, or Scythians. Their physiognomy seems to indicate a Semitic origin, while their worship of Set connects them with the Khita, a people to the n. of Palestine, on the confines of Mesopotamia. The names of the kings exhibit no foreign peculiarities; some are purely Egyptian. As regards the date of the Hykshos dominion, the most conflicting opinions have prevailed amongst scholars. Bunsen makes their rule end 1639 B.C.; Lepsius, 1842 B.C. Placing, however, the discovered date of Thothmes III., 1445 B.C., in his 16th year, the close of Hykshos dominion must have ended about 1500 B.C.

Bunsen, *Egypt's Place*, vol. ii. pp. 405, 578; Lepsius, *Königsbuch;* Boïkh, Manetho, p. 231; De Verria, *Rev. Arch.* (1861), vol. iv. p. 249; Mariette, *Rev. Arch.* (1861), vol. iii pp. 97, 247, 337.

HYLÆOSAU'RUS (Gr. forest-lizard), a huge dinosaurian reptile, found in the Wealden strata of Kent and Sussex. Fragments of different individuals have been found sufficient to give an approximate notion of the affinities and great size of this reptile. The bones of the head have not yet been observed; its teeth were comparatively small, and close set; they seem to indicate that it was a vegetable eater. The body was broader than high, and terminated in a long slender flexible tail; the limbs were relatively short; the skin was covered with scutes and tubercles; and a row of very large thin angular bony spines extended down the back, and formed a serrated dermal crest, like the horny spines of the modern iguana. It is supposed to have attained a length of 25 feet. The remains of only one species have been found; it has been named *H. Oweni.*

HY'LIDÆ. See TREE FROGS, *ante.*

HYLOBATES. See GIBBON, QUADRUMANA, and VERTEBRATA.

HY'MEN, or HYMENÆ'US, in Grecian mythology, the god of marriage; but originally, the word seems to have denoted only the bridal-song which was sung by the companions of the bride as she went from her father's house to that of the bridegroom. The god Hymen is first mentioned by Sappho. The legends concerning him are various; but he is generally said to be a son of Apollo and some one of the Muses. He is represented as a boy with wings and a garland, a bigger and graver Cupid, with a bridal-torch and a veil in his hands.

HYMENOP'TERA (Gr. membrane-winged), an order of insects, containing a very great number of species, estimated at about one-fourth of the whole class, and of which some, as ants and bees, are singularly interesting and important. They have the mouth furnished with mandibles for cutting and tearing, but the other parts of the mouth are adapted for suction, and are generally narrow and elongated, often united into a kind of proboscis, as in bees. See BEE. The antennæ are generally slender, but often exhibit differences in the sexes of the same species. The wings are four in number, the first pair larger than the second, the wings of the same side united in flight by little hooks. The wings, when at rest, are laid one over another horizontally over the body. The wings are entirely membranous, not reticulated as in the *neuroptera*, but with comparatively few nervures, the arrangement of which is so constant in the whole order that particular names have been given to them and to the space between them, and their diversities have been made use of in classification. The wings are wanting in the imperfectly developed females (*neuters*) of some. Besides the ordinary eyes, all the hymenoptera have three small simple (or *stemmatic*) eyes on the top of the head. The abdomen is generally united to the thorax by a slender pedicel. The abdomen of the females is generally furnished with an organ capable of being protruded, but for different purposes in different sections of the order, it being in some of the hymenopterous tribes an ovipositor or borer, and in others

a sting. The hymenoptera in their perfect state generally feed on honey, but some of them prey on other insects, which are the food of the larvæ of a greater number; whilst the larvæ of some feed on various vegetable substances. The metamorphoses of the insects of this order are perfect; the larvæ are generally—although not in all the families—destitute of feet; the pupæ take no food. The hymenoptera are remarkable for the dilatation of the *trachea* or air-tubes into vesicles, and the general perfection of the respiratory system. The instincts and even apparent intelligence displayed by some of them—particularly the *social* kinds, which live in communities—have excited admiration from the earliest times.—The order is divided into two sections: *terebrantia*, having an ovipositor; and *aculeata*, having a poison-reservoir and sting. To the former belong saw-flies, gall-flies, ichneumons, etc.; to the latter belong ants, bees, wasps, etc.

HYMET'TUS, a mountain in Attica, now called Trelo Vouni, situated to the s.e. of Athens, and famous among the ancients for its honey and its marble. The honey still retains its reputation.

HYMN, a canticle of praise or of prayer addressed to the divine honor. The word in its strict acceptation supposes a certain metrical structure, or at least some kind of rhythmical cadence. The use of hymns dates from the earliest days of Christianity (Matt. xxvi. 30; Col. iii. 16); but our information as to the hymns of the early ages, and still more as to their authors, is extremely imperfect. The *Te Deum* is variously ascribed to St. Ambrose, St. Hilary, to Abundius, and to a monk named Sissabul. To Prudentius, with greater certainty, are assigned the *Hymn of Holy Innocents, Salvete Flores Martyrum*, and the *Ales Diei Nuntius*. Even the names of the authors of the more modern hymns are often involved in mystery; but some of the most esteemed hymns are known as the productions of Sedulius, of Fortunatus, of Paul the deacon, of St. Bernard, and St. Thomas. The number of hymn-writers in the modern languages is so great as to preclude the possibility of any enumeration. The most complete modern collection of mediæval Latin hymns is Mone's *Hymni Latini Medii Ævi* (1856).

HYMNOLOGY (HYMN, *ante*). I. *Scripture psalms and hymns.* The sacred writings record strains of poetry, music, and song which furnish a model for the praises of the church through the ages. The book of Job, generally regarded as the oldest, declares that, at the creation, "the morning stars sang together and all the sons of God shouted for joy." Moses led Israel into the wilderness with a song of praise—"I will sing unto the Lord, for he hath triumphed gloriously"—and brought them to the end of it with a doxology—"There is none like the God of Jeshurun, who rideth on the heaven in thy help." Centuries after, during troublous times, Deborah's song mingled a woman's tenderness with a warrior's joy—"Lord, when thou wentest out of Seir, the earth trembled and the heavens dropped." Afterwards Hannah's song is given—"The Lord maketh poor and maketh rich." From the heights of Bethel, in Samuel's day, "a company of prophets came down with psaltery and tabret, and pipe and harp." David, the sweet singer of Israel, composed among his flocks the psalm, "The Lord is my shepherd;" and, when he brought up the ark to Zion, appointed Levites, with instruments of music, to sing, in the worship of the sanctuary, "Give unto the Lord, ye kindreds of the people, give unto the Lord glory and strength." With David other psalmists were united; and yet others, ages after, added to their work. From the depths of the captivity came the mournful strain, "By the rivers of Babylon there we sat down," followed with thanksgiving when the captivity was turned. The Psalms completed have filled with the voice of praise not only the Jewish temple, but also the sanctuaries of all lands where the Lord is worshiped. The voices of the prophets repeated and prolonged the songs of Moses, "God came from Teman and the Holy One from Mount Paran; his glory covered the heavens, the earth was full of his praise." After long silence their last promise was caught up by Zacharias, "Thou, child, shalt go before the face of the Lord to prepare his way;" and Hannah's thanksgiving was renewed, in even gentler tones, from Mary's lips, "He hath put down the mighty and exalted them of low degree." Soon, on the plains of Bethlehem, glad tidings of great joy for all people were proclaimed, and that song of the angels was heard which has floated down the centuries, "Glory to God in the highest, and on earth peace, good will toward men." Mingled with these were various human songs, from that of Simeon, "Lord, let thy servant now depart in peace," on to the hosannas on the mount of Olives and in the temple, the hymn at the institution of the supper, and the ascriptions of praise after the ascension. In the prison of Philippi praises to God were sung at midnight; in the early Christian worship, psalms, hymns, and spiritual songs were directed to be habitually used; and, in the closing of the Revelation, some of the songs of heaven were sent down to instruct and comfort the church on earth: the ascription of holiness and sovereignty to God, "Holy, holy, holy, Lord God almighty;" the song of redemption, "Worthy is the Lamb that was slain;" the song of Moses and the Lamb, "Great and marvelous are thy works;" and the wedding-song of the church in heaven, the bride of Christ, "Alleluia, for the Lord God omnipotent reigneth." II. *Hymns of the ancient Christian church.* Basil quotes an evening hymn from an unknown author. Pliny the younger, at the beginning of the 2d c., in describing Christians by characteristic marks, says that they were accustomed to sing hymns to Christ as to God. The oldest hymn that remains complete from the period of persecution is that of Clement of

Alexandria, which, though not remarkable as a poetical production, gives utterance to the emotions of love and thankfulness to Christ which filled the hearts of the early believers. Many of the Gnostics composed sacred songs in imitation of orthodox Christians as a popular means of diffusing their doctrinal views. One of these, Bardesanes, in the Syrian church of the 2d c., wrote 150 to correspond in number with the Psalms, which he imitated also in style and structure, thus "presenting to simple souls a poisonous cup tempered with seductive sweetness." Ephraem Syrus, on the other hand, representing the Syrian hymnology, endeavored to counteract the Gnostic songs. In the Greek church, Arius, like the Gnostics, wrote hymns "for the sea, the mill, and the highway, which he set to music," and, by the practical Christian spirit which he infused into them, made them more popular than those of the orthodox church. Chrysostom endeavored to neutralize their influence in Constantinople by productions of his own pen. So general was the diffusion of these various songs that Jerome says no one could go into the fields without hearing the plowman singing hallelujahs, the mower hymns, and the vine-dresser David's psalms. The Greek sacred poetry, the work of nine centuries, has been, in a great degree, restricted to the oriental church. Most of it, pervaded with the superstitions of the east, is unfitted for general use. Some of the most valuable, however, has lately been well translated into English by Neale. The hymns of the Latin church are greatly superior in evangelical qualities to those of the Greek. The best of them, through translations and paraphrases, have become familiar in Protestant churches. The most celebrated one is *Te deum laudamus*, sung over all Christendom, and generally attributed to Ambrose, bishop of Milan, about 370 A.D., though some critics now assign it variously to other authors of later date. Many of the Latin hymns, however, like the Greek, celebrate the praises of Mary and the martyrs, and for Protestant ears are marred by various superstitious errors. The famous one of Thomas Aquinas, *Pange, lingua, gloriosi*, it has been said, "fixes the epoch of transubstantiation, the point at which the rhetoric of the pulpits froze into the logic of the schools." During the middle ages large numbers of hymns were written in the cloisters of Germany and France. The authorship of some of the best is uncertain or unknown. *Veni, Creator Spiritus*, translated by Dryden, has been ascribed by some to Charlemagne and by others to Maurus. The *Dies Iræ* was written by Thomas of Celano, and the *Stabat Mater* by Jacopone. III. *Modern hymns.* 1. *German.* The earliest known German hymns belong to the 9th c., at which time, in a few churches, the people continued the old practice of joining in the response *Kyrie eleison* at certain intervals during the singing of the Latin hymns. To this were added a few German rhymes which constituted their earliest hymns, but were restricted at first to popular festivals and pilgrimages. In the 12th c. sacred songs in the national language were more freely written. Some translations also from the Latin became favorites among the people. But while a part of the German hymns were evangelical, others, like many of the Greek and Latin, were extravagant ascriptions to the virgin Mary of the attributes belonging to her divine son. Hymns in the national language were largely used also, by the Flagellants, Bohemians, Waldenses, and other sects, in connection with their study of the Scriptures. The reformation produced a great revival of sacred song throughout Germany as a natural accompaniment of liberty to worship God in the national language and to read his word. Luther not only translated the Bible, but also labored to make the practice and knowledge of music general throughout the land. Besides newly translating many of the best Latin hymns, he was himself the author of more than twenty, most of which have been widely diffused among Protestant nations, some of them being special favorites with all English speaking people. His *Ein feste Burg ist unser Gott*, Heine called the *Marseillaise* of the reformation. The thirty years' war, with all its disasters and sorrows, greatly stimulated the activity of the German mind and produced "a great outburst of religious song" from famous authors, among whom were Opitz, Fleming, Rist, Heermann, and, a little later, Gerhardt, the prince of German hymnists, whose songs are "pervaded by a spirit of cheerful piety showing itself alike in love to God and Christ, to nature, and to mankind." After him followed Frank, Neumark, Silesius, and other well-known names. The school of pietists, which for nearly a hundred years exerted a powerful influence on the religious and social life of Germany, furnished also some celebrated writers of hymns, among whom were Spener and Freylinghausen. The latter published a collection which was cherished by pious persons for several generations. In South Germany Hiller's *Spiritual Songs* was very popular, and is said to be "still the commonest book in Würtemberg next to the Bible." Among the mystics, Arnold and Tersteegen have written some hymns which are justly esteemed. Among the Moravians count Zinzendorf was remarkable as the author of more than 2,000 hymns, some of which are excellent. The prevalence of rationalism in Germany was unfavorable to hymnology. In connection with the "critical doubting" there "sprang up a mania for altering the classical hymns, consecrated, as they were, by so many associations." The alterations consisted in weakening the old strength and changing religion into mere morality. The process was popularly known as "hymn-book watering." It was, however, only partially successful. Often the genuine emotion produced by the singing prevailed over the rationalism of the pulpit. Among the evangelical poets of the time, Gellert, Klopstock, and Cramer are justly esteemed. In South Germany and Austria great progress was marked by the permission which was

officially given to use vernacular hymns in the Roman Catholic churches. Though many of those adopted were translations from the Latin, yet in the original compositions the style of Gellert and Klopstock was imitated, and some of their hymns, even, were introduced. At the present time the reaction from rationalism is marked by a corresponding improvement in the style and quality of the hymns. The German evangelical church has produced in all about 80,000 devotional songs of various sorts and grades. 2. *French.* The Roman Catholic church of France continues to use in its public choral worship the old language of the Vulgate and the Breviary. The sacred songs of Madame Guyon give expression to the deep religious experience, abounding in peace and joy, which, as Wesley says, she truly possessed notwithstanding her errors of opinion and the sufferings brought on herself by her great mistake in following, as inspirations, her own inward impressions, instead of the directions of the written word. In later times, hymns in the French language have been freely used among the lower classes by Roman Catholic missionaries who, learning wisdom from Protestantism, employ against it one of its own chosen instrumentalities. The Reformed French church retains its version of the Psalms which, commenced by Marot in the early part of the 16th c., and finished by Beza, exerted great influence on the religion of the land. Its words, set to native airs, were cherished in the hearts of the people and were sung in the crowded cities, in the vineyards, on the rivers, and even during hunting expeditions of the king. Thus it powerfully aided the work of the reformation. In recent times, Cæsar Malan of Geneva has written many excellent hymns which express warm devotional feeling and clear scriptural truth in simple and flowing verse. Vinet also, in addition to his eminent attainments as a preacher and teacher of theology, was the author of a few hymns that well exhibit the thoughtful and ardent spirituality of his nature. 3. *English.* In England there has been a great deal of sacred poetry that cannot strictly be called hymns. The publications of the Percy society contain specimens of devotional song that are ascribed to the 13th c., and the reign of Edward I. In the 14th c., Chaucer, "the father of English poetry" in its other branches, also "made many a hymn for holy days." After him no eminent poets appeared until the age of Elizabeth, during which the production of sacred verse was greatly increased. Among the writers of it were queen Elizabeth, archbishop Parker, Edmund Spenser, sir Walter Raleigh, lord Bacon, and sir Philip Sydney—joint author with his sister, the countess of Pembroke, of a metrical version of the Psalms. Another version, commenced by Sternhold and finished about 1562 by Hopkins with some assistance from other authors, though deficient in refinement and inferior in other respects, was marked by rugged strength as well as bold harmony and contained some stanzas which are still greatly admired. It became popular and, appended to the book of common prayer, continued long in use. The 17th c. produced the saintly Herbert, the quaint old Quarles with Vaughan, Southwell, and, above all, Milton, who, in addition to *Paradise Lost*, was the author of a noble Christmas hymn and other sacred lyrics. The dramatists also of that age, Ben Jonson, Beaumont, Fletcher, and, greatest of all, the "myriad-minded" Shakespeare, furnished many specimens of sacred poetry which show the influence of Christianity on their intellects and hearts. The version of the Psalms by Rouse, an English Puritan, commended by the house of commons to the Westminster assembly and published in 1646, was generally used by British Presbyterians of that day and still holds its place in many of their congregations both in the old world and the new. At the close of the c., Tate and Brady's version was made, and, although "inflated, smooth, and insipid," soon superseded Sternhold and Hopkins as an appendage to the prayer book, which it still continues to be. Ten years before it, Mason's *Spiritual Songs* appeared, excellent in themselves and destined to prepare the way for still nobler strains that were soon afterwards heard. Dr. Watts, it is said, owed much to them. During all the time thus briefly reviewed, in the English cathedrals and other churches besides the Psalter, the Glorias, Te Deum, and some hymns of the middle ages, continued to be sung. On the threshold of the 18th c. bishop Ken's morning hymn, beginning with *Awake my Soul*, and closing with the doxology, *Praise God from whom all blessings flow*, entered on that stage of duty which now, like the sun, encircles the earth. About the same time Isaac Watts wrote for a single congregation the first of the "songs before unknown," many of which have been cordially adopted by nearly all denominations of Protestant Christians. His cradle hymn has been sung in myriads of homes, and his divine songs for children, charming to them, have been acceptable to men of gifted minds. It is a pleasing coincidence that Ken's doxology and Watts's spiritual songs, which are now sung together in so many churches of different lands, together also marked the advent of modern English hymns. Doddridge was a child when the hymns of Watts were published, and, having become much attached to them, derived from them, it may be supposed, something of the poetic and devotional feeling which is expressed in his own hymns, many of which have entered into the life of the evangelical churches. Charles Wesley, a few years younger than Doddridge, became intimately connected with his older brother in the labors of the Methodist itineracy, and, during intervals of toil, wrote 7,000 hymns, many of which are highly esteemed for their lyrical excellence, religious fervor, and varied Christian experience. They owe much of their success, also, to the influence of the great revival of religion, in the midst of which he labored and which they, in their turn, so largely promoted. Some of them are rendered more interesting by the peculiar circumstances

which suggested them. At the beginning of his Christian life, while shrinking back from a public profession of his faith, a friend said to him: "If you had a thousand tongues you should publish the gospel with them all." This led to the hymn, *Oh for a thousand tongues to sing.* Standing on the extreme projection of Land's End, he wrote, *Lo! on a narrow neck of land.* His judgment hymn was written just after the earthquake which destroyed Lisbon. Toplady, widely separated from the Wesleys in theological opinion, has been closely united with them in influence by his *Rock of Ages, cleft for me.* After these came Olivers, Cennick, Beddome, the countess of Blessington, and Annie Steele. The Olney hymns, by Newton and Cowper, contain among many other favorites, *Amazing grace, how sweet the sound; How sweet the name of Jesus sounds;* and *Sometimes a light surprises,* written by the former; and by the latter *Oh for a closer walk with God; There is a fountain filled with blood;* and *God moves in a mysterious way.* Robinson wrote *Come thou fount of every blessing;* Logan, *Where high the heavenly temple stands;* Medley, *Awake my soul in joyful lays;* Kirk White, *The Lord our God is full of might;* Perronet, *All hail the power of Jesus' name;* Thomas Moore, *Come, ye disconsolate.* James Montgomery, a Moravian Christian and a gifted poet, has enriched English hymnology with precious songs too numerous to be specified and too highly valued by the church at large to need commendation here. Lyte is the author of *Jesus! I my cross have taken;* Sarah F. Adams, of *Nearer my God to thee;* Charlotte Elliott, of *Just as I am without one plea;* sir John Bowring, of *In the cross of Christ I glory;* bishop Heber, of *From Greenland's icy mountains.* Keble's *Christian Year,* while it contains many hymns that are precious to all Christians, is said to have contributed greatly to the success of *Tracts for the Times.* "In its pensive, dreamy, soothing strains, we have the logic of the Oxford schools turned into rhetoric. The academic cloister and the Gothic aisle are the haunt and main region of his song. The white Levitical vestment is his singing robe, and you listen, in the dim religious light, to a music like the lulling chime of church bells." 4. *American.* The first American edition of Watts's Psalms and Hymns was published in 1741 by Benjamin Franklin, then a Philadelphia printer and comparatively unknown. These among Congregational, Baptist, and Presbyterian churches, with a collection of Wesley's hymns among Methodists, were, for many years, almost the only books in general use. In 1800 president Dwight, at the request of the general association (Congregational) of Connecticut, prepared an edition of Watts, with many additional hymns, some of which, from his own pen, are of great value. Among these are: *I love thy kingdom, Lord,* and *While life prolongs its precious light.* In 1818 Dr. Worcester of Salem, Mass., added to the unchanged Watts a copious selection of the best hymns then accessible. In 1830 Dr. Leavitt's *Christian Lyre* appeared; in 1831, *Church Psalmody,* by Dr. Lowell Mason and rev. David Green; in 1832, *Spiritual Songs,* by Drs. Mason and Hastings; in 1858, the Plymouth collection, by rev. Henry Ward Beecher, and the Sabbath Hymn Book, by profs. Park and Phelps, and Dr. Mason. By that time all the barriers had given way and new hymn books have since been introduced among all denominations. In these various collections, besides the productions of English authors already mentioned, there are many choice American hymns. Among these may be cited: *Softly now the light of day,* and *Rising out the banner, let it float,* by bishop Doane of New Jersey; *I would not live alway,* by Dr. Muhlenbergh; *How beauteous were the marks divine,* and *Oh! where are kings and empires now,* by bishop Coxe; *Oh sacred head, now wounded,* translated by Dr. James W. Alexander from Gerhardt's German hymn; *It is not death to die,* by Dr. Bethune; *My faith looks up to thee,* and *Jesus! these eyes have never seen,* by Dr. Ray Palmer; *Blest comforter divine,* by Mrs. Sigourney; *One sweetly, solemn thought,* by Phœbe Carey; *I love to steal awhile away,* by Mrs. Phœbe H. Brown. These and many more have greatly enlarged the list of psalms, hymns, and spiritual songs, in which the Christian church of all denominations can now worthily sing praises to the Lord. And, during all these years of advancement in hymns for the church, great attention, also, has been given to providing special hymns for children. The collections of these are very numerous and of various degrees of merit—few, however, of highest rank. Among the earliest was Bradbury's *Golden Chain,* and among the latest is Dr. Charles S. Robinson's *Spiritual Songs for Sabbath Schools.* In general, the public taste in hymnology is growing more critical, and demands are heard from various quarters for a disregarding of many of the hymns which have swollen recent hymn-books to such great proportions. It is claimed that good prose is better than poor poetry, and that when devotion calls art to its service it should secure at least sufficient art to produce correct rhyme and rhythm.

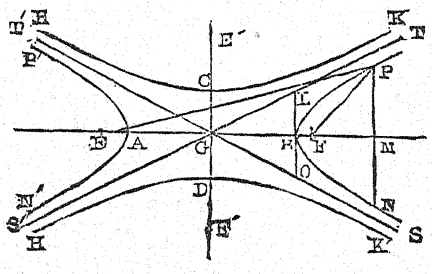
HYOID BONE, the tongue bone, or V-shaped bone, so named from its resemblance to the Greek letter *upsilon.* It is sometimes spoken of as unimportant in man, compared to the so-called hyoid bone in many of the lower animals, in which, on account of its being a support for branchial apparatus, it is often developed to a great size. But its importance is no less in man, because of its connection with the principal lingual organ; the perfection of its form and its exact location at the base of the tongue being a considerable element in the apparatus for the formation of articulate and musical sounds.

HYOSCY'AMUS. See HENBANE

HYPA'TIA, daughter of Theon, an astronomer and mathematician of Alexandria, and head of the Neo-Platonic school in that city, was b. in the latter part of the 4th century. She was equally remarkable for her beauty, her wisdom, and her tragic fate. From her earliest youth, she exhibited an amazing intelligence, in consequence of which, her father, one of the most erudite savants of his time, resolved to give her genius a thoroughly philosophic culture. She succeeded her father in the chair of philosophy at Alexandria; and the fame of her lectures drew round her students from all parts of the east where the influence of Greek thought and knowledge was felt. Hypatia seems to have been worthy of the lofty eulogies she has received. Amid the wide-spread corruptions of Alexandria she lived as spotless as a vestal; and if her teaching was not one that could lay a strong hand on the vices of heathenism, and arrest their course, it was at least sufficient not only to preserve herself from pollution, but also to inspire her with a love of beauty, truth, and goodness, that was Christian in its spirit and earnestness, in heathen in its form and limitations. The citizens of Alexandria were proud of her; and such reliance was placed on her judgment and sagacity, that the magistrates used frequently to consult her on important cases. Among those who were most intimate with her was Orestes, prefect of the city. At this time the bishop of Alexandria was Cyril (q.v.), a fierce hater of heathens and heretics. Detesting Orestes, whom he suspected of being no true Christian, and who had drawn up an accusation against him for exciting a tumult, he soon cast an evil eye on Hypatia, whom he regarded as a satanic enchantress, and the grand obstacle to his reconciliation with the prefect. His hatred communicated itself to the lower clergy, and especially to certain savage monks from the Nitrian deserts, who, headed by one Peter, a reader, attacked Hypatia in the streets as she was returning from her lecture-room. The maiden was dragged from her chariot, hurried to the Cæsarian church, where she was stripped naked, and murdered with tiles, after which she was torn to pieces, and her limbs carried to a place called Cinaron, and there burned to ashes, 415 A.D. Hypatia is the heroine of Charles Kingsley's *Hypatia, or New Foes with an Old Face.*

HYPERÆSTHE'SIA (derived from *hyper*, over, and *aisthēsis*, a sensation) include those affections which have this property in common—viz., an exalted irritability and increased irritation of the nerves. Hyperæsthesia of the cutaneous nerves is manifested by pain in its various modifications, which is sometimes intensely severe, as in tic-douloureux (q.v.), while hyperæsthesia of the nerves of special sense is manifested by phantasms, illusions, etc. The following points are common to the whole class of these affections: 1. Periodicity, or the alternations of paroxysms and intermissions; 2. Uniformity and persistence of the symptoms, however long the duration of the disease; 3. No danger to life; 4. Freedom from this class of diseases in early life. Of the diseases predisposing to hyperæsthesia, hysteria is far the most frequent; but it is sometimes induced by rheumatism, gout, skin-diseases, etc.

HYPER'BOLA. If two similar cones be placed apex to apex, and with the lines joining the apex and center of base in each, in a straight line; then if a plane which does not pass through the apex be made to cut both cones, each of the two sections will be a *hyperbola*, as PBN, P'AN'. It is, viewed analytically, the locus of the point to which the straight lines EP, FP differing by a constant quantity are drawn from two given points, E and F. These given points are called the *foci*, one being situated in each hyperbola. The point G, midway between the two foci, is called the *center*, and the line EF the *transverse axis* of the hyperbola. A line through G perpendicular to the transverse axis is called the *conjugate axis;* and a circle described from center B, with a radius equal to FG, will cut the conjugate axis in C and D. If G be taken for the origin of co-ordinates, and EM and E'F' for the axis, the hyperbola is expressed by the equation $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$. (GB=$a$, GC=$b$). The hyperbola is the only conic section which has asymptotes (q.v.); in the figure these are GT, GT'; GS, GS'. It also appears that if the axis of co-ordinates be turned at right angles to their former position, two additional curves, HCK, H'DK', will be formed, whose equation is $\frac{x^2}{b^2} - \frac{y^2}{a^2} = 1$. These two are called *conjugate hyberbolas*, and have the same asymptotes as the original hyperbolas. These asymptotes have the following remarkable property: If (starting from G) the asymptotes be divided in continued proportion, and from the points of section lines be drawn parallel to the other asymptote, the areas contained by two adjacent parallels and the corresponding parts of the asymptote and curve are equal; also lines drawn from the center to two adjacent points of section of the curve, inclose equal areas. The equation to the hyperbola when referred to the asymptotes is



$xy=ab$; which shows that as the ordinates decrease in geometrical progression, the abscissæ increase in the same ratio.

HYPER'BOLÉ (Gr. *hyper*, over, and *ballein*, to throw) is the name given to a figure of rhetoric, by which expressions are employed that, taken literally, signify more than is really meant. The use of the figure is to arrest the attention. Hyperbole is the basis of many metaphors. Thus, we call Nero a "monster;" Tamerlane, a "tiger;" and so on.

HYPERBO'REANS (that is, dwellers beyond Boreas or the North Wind), a name given by the ancients to all the unknown peoples of the west and north. The Greeks imagined the country n. of the Rhipæan (generally supposed to be the Ural) mountains to be inhabited by the Hyperboreans, and their residence was gradually referred to more distant regions; but it was universally supposed that, as the favorites of Apollo, they enjoyed a terrestrial paradise, a bright sky, and a perpetual spring, a fruitful land, and everlasting youth and health.

HYPERICA'CEÆ, or HYPERICI'NÆ, a natural order of exogenous plants, containing about 300 known species, trees, shrubs, and herbaceous plants, widely distributed over the world, and in very different climates, but particularly numerous in North America. The leaves are generally covered with pellucid dots, and the edges of the leaves, sepals, and petals bordered with black glands. The stamens are united at the base, and grouped in from 3 to 5 bundles.—The species of *vismia* yield a substance resembling gamboge. Many of the hypericaceæ belong to the genus *hypericum*, or St. John's wort, of which some species are common natives of Britain, adorning woods, heaths, etc., with their bright yellow flowers. *H. calycinum*, a spreading shrubby species, naturalized in some places in Britain, has flowers more than 2 in. in diameter. *H. perforatum*, the common or true St. John's wort, has astringent properties, and is used for gargles and lotions, and internally in dysentery, etc., although not recognized in the pharmacopœia. Superstitious notions are connected with it in many parts of Europe, particularly when gathered on the day of St. John the Baptist.—*H. androsæmum* (or *androsæmum officinale*), commonly called tutsan, a pretty common native of Britain, with berry-like fruit, was once in great esteem as a vulnerary. Its English name is *tutsan*, from the French *tout saint*, all whole.

HYPERI'DES, an Athenian orator, one of the ten comprised in the Alexandrian canon; the contemporary of Demosthenes. After studying philosophy under Plato, and oratory under Isocrates, he began his public career as an advocate in the Athenian courts of justice, and joined the patriotic party, at that time led by Demosthenes and Lycurgus. He fitted out two triremes at his own expense for the Eubœan expedition of B.C. 358. His whole public life, for the next 20 years, was spent in devising means of resistance to the growing power of Macedonia. In 338 B.C., when the disastrous fight of Chæronea laid Greece at the mercy of Philip, Hyperides proposed that the citizens should send their wives and children to places of security, and fight it out to the last. Though this desperate advice was not taken, its genuine patriotism was appreciated and rewarded by his countrymen. When the death of Philip revived the hopes of the anti-Macedonian faction, Hyperides promoted the alliance with Thebes; and after the destruction of that city by Alexander, was one of the orators demanded of the Athenians by the young victor. Alexander, however, did not press his demand, and Hyperides continued to oppose the Macedonian influence as strongly as ever. The arrival in Athens of Harpalus, the run-away treasurer of Alexander, then absent on his eastern conquests, disturbed the friendly relation that had hitherto subsisted between Hyperides and Demosthenes. Harpalus had embezzled 5,000 talents of the public money, with which he endeavored to organize a party for himself among the Athenians. It was believed that, among others, Demosthenes had yielded to his bribes and specious stories, and Hyperides was selected to prosecute his ancient friend. This led to a rupture, which was not healed for some time. In the Lamian war, which followed the death of Alexander, Hyperides took a leading part; and when it was brought to a close, spoke the funeral oration over his countrymen who had perished in battle. This oration was looked upon as a masterpiece by the ancients. The following year (B.C. 322) saw the hopes of Athens finally crushed at the battle of Crannon. The chiefs of the patriotic party sought safety in flight. Hyperides was overtaken at Ægina by the minions of Antipater, and put to death. Seventy-five orations were attributed to Hyperides; but a third of these were rejected as spurious by the ancients themselves. Westermann has preserved the titles of sixty-one of these in his *History of Greek Oratory*.

HYPE'RION. See TITANS.

HY'PERSTHENE, a mineral closely related to augite and diallage. It is a bisilicate of iron and magnesia. It is crystalline, but often found granular or disseminated. Viewed in one direction, with reference to its cleavage planes, it is copper-colored, in another it is dark brown. When cut and polished, it is cherry-red, with a pearly luster, and is valued for rings, brooches, etc. The finest specimens are brought from the coast of Labrador, although it is found in Norway, Sweden, Germany, Scotland, etc. It is sometimes found in connection with feldspar, forming *hypersthene rock*, a rare kind of trap rock.

HYPER'TROPHY (Gr. over-nourishment) is the term applied in medicine to the enlargement of certain organs of the body. The best examples of this change are seen in the muscular system, where it may occur altogether independently of disease. The hugh bosses of flesh that stand prominently forward in the arm of a blacksmith or of a pugilist, and in the leg of an opera-dancer, are illustrations of hypertrophy, where the general health may be perfect. In double organs, such as the kidneys and lungs, if the organ on one side degenerates through disease, the organ on the opposite side is often found to enlarge, and carry on double work. In these cases, hypertrophy is an effect of disease, but is at the same time a resource of nature to preserve life.

There are, however, cases in which the hypertrophy has a hurtful instead of a conservative effect, as, for example, hypertrophy of the thyroid gland, constituting the disease known as goitre or bronchocele, hypertrophy of the prostate gland, of the spleen, etc. The following are, according to Mr. Paget, the conditions which give rise to hypertrophy: 1. The increased exercise of a part in its healthy function; 2. An increased accumulation, in the blood, of the particular materials which a part appropriates in its nutrition or in secretion; 3. An increased afflux of healthy blood. In hypertrophy of the muscular tissue, the first and third of these conditions are present. In hypertrophy of the fatty tissue, constituting obesity, there is an excess of fat or its chief elements in the blood.

HY'PHASIS. See SUTLEJ.

HY'PHEN (Gr. together, in one), the name given to a mark in writing, thus (-), indicating that two words or syllables are to be connected; e.g., bull-fight.

HYP'NOTISM (from the Greek word *hypnos*, sleep) is a term invented by the late Mr. Braid, of Manchester, to designate certain phenomena of the nervous system which in many respects resemble those which are induced by animal magnetism, but which clearly arise from the physical and psychical condition of the patient, and not from any emanation proceeding from others. The following are his directions for inducing the phenomena, and especially the peculiar sleep-like condition of hypnotism. Take a silver lancet-case or other bright object, and hold it between the fingers of the left hand, about a foot from the eyes of the person experimented on, in such a position above the forehead as to produce the greatest strain on the eyes compatible with a steady fixed stare at the object. The patient must be directed to rivet his mind on the object at which he is gazing. His pupils will first contract, but soon dilate considerably; and if, after they are well dilated, the first and second fingers of the operator's right hand, extended and a little separated, are carried from the object towards the eyes, the eyelids will most probably close with a vibratory motion. After 10 or 15 seconds have elapsed, it will be found that the patient retains his arms and legs in any position in which the operator places them. It will also be found that all the special senses, excepting sight, are at first extremely exalted, as also are the muscular sense and the sensibility of heat and cold; but after a time the exaltation of function is followed by a state of depression far greater than the torpor of natural sleep. The patient is now thoroughly hypnotized. The rigidity of the muscles and the profound torpor of the nervous system may be instantly removed and an opposite condition induced by directing a current of air against the muscles which we wish to render limber, or the organ we wish to excite to action; and then by mere repose the senses will speedily regain their original condition. If a current of air directed against the face is not sufficient to arouse the patient, pressure and friction should be applied to the eyelids, and the arm or leg sharply struck with the open hand.

From the careful analysis of a large number of experiments, Mr. Braid is led to the conclusion that by a continual fixation of the mental and visual eye upon an object, with absolute repose of body and general quietude, a feeling of stupor supervenes, which renders the patient liable to be readily affected in the manner already described. As the experiment succeeds with the blind, he considers that "it is not so much the optic, as the sentient, motor, and sympathetic nerves, and the mind, through which the impression is made."

Many of the minor operations of surgery have been performed on patients in the hypnotized state without pain, and hypnotism has been successfully employed as a therapeutic agent in numerous forms of disease, especially such as have their seat in the nervous system. An interesting memoir *On Hypnotic Therapeutics* was published by Mr. Braid in the 17th volume of *The Monthly Journal of Medical Science* (1853).

HYP'NUM, a genus of mosses, which contains many of the most common British species, growing on moist ground, in woods, on old trees, etc. Many species have stems of considerable length and much branched. The fruit-stalk springs from a lateral tubercle. The *peristome* (see MOSSES) is double, the exterior of 16 teeth, the interior a membrane divided into 16 segments, with alternate cilia.

HYP'OCAUST, a form of furnace much used by the Romans, for the purpose of heating baths and apartments. The fuel is placed in a chamber under the floor, and the smoke and heated air are made to circulate round the walls and under the floor, by means of hollow tubes, or a hollow lining. The full benefit of the fire is thus obtained, in place of a large portion of the heat being allowed to escape, as it does, in the case of

an open fireplace, up the chimney. The Romans invariably used this form of furnace for heating their dwelling-houses, and in all the Roman houses which have been discovered in this country, remains have been found of the hypocaust. It is now coming again into use for heating the so-called "turkish baths."

HYPOCHÆ'RIS, a genus of plants of the natural order *compositæ*, sub-order *cichoraceæ*, of which one species, *H. radicata*, or long-rooted cat's-ear, is extremely common in meadows and pastures in Britain. Its leaves are all radical, and spread on the ground, resembling in form those of the dandelion, but rough; the stem is branched, the flowers not unlike those of the dandelion, but smaller. Cattle eat this plant readily, and its abundance is not deemed injurious to pasture or fodder.

HYPOCHLO'ROUS ACID (ClO) is a dark red fluid, which, at a temperature of about 70°, becomes converted into an orange-colored gas, which very readily explodes into its ultimate constituents. A watery solution of this gas has a penetrating, chlorine-like odor, a caustic action on the tongue, colors the skin brown, and if applied for any length of time, causes it to ulcerate. It is the active ingredient of the different bleaching-powders and salts. Its salts—the hypochlorites—present very much the same odor as the acid. Their solutions bleach organic pigments, such as litmus and indigo, and are employed largely as bleaching agents

HYPOCHON'DERS (Gr. *hypo*, under; *chondros*, a cartilage) are the two lateral and superior regions of the abdomen (q.v.) under the cartilages of the false ribs, and to the right and left of the epigastrium.

HYPOCHONDRI'ASIS (so called from its supposed connection with the hypochondriac regions of the abdomen), a disease characterized by extreme increase of sensibility, palpitations, morbid feelings that simulate the greater part of diseases, exaggerated uneasiness and anxiety, chiefly in what concerns the health, etc. In extreme cases it becomes a species of insanity (see below). The disease is intimately connected with, if not caused by, disorder of the digestive functions. See INDIGESTION.

Hypochondriacal Insanity.—When somberness of disposition and anxiety concerning personal comfort become exaggerated, and attention is directed chiefly to the state of the health, it amounts to common hypochondriasis. When it passes beyond the control of the will, when the whole mind is directed to the state of the system, or to particular organs, and exalts and misinterprets sensations, the condition is designated hypochondriacal insanity. The disease may be described as the engrossment of the attention by false impressions conveyed, or conceived to be conveyed, from internal organs. These sensations may, in many instances, be real, and proceed from actual alterations in the structure or functions of the parts supposed to be affected; but they may likewise consist of ordinary sensations, excited and intensified by the act of attention which makes them known to the patient. Neither the experience nor the sufferings of the victims are imaginary, however absurd their errors, and however groundless their apprehensions may be; the disease consists in the exaltation of sensibility and attention, and in the delusions which originate in that morbid state. A man lives in constant fear of death; he is firmly convinced that he labors under cancer, consumption, disease of the heart, and lives upon drugs; that his stomach, or bowels, are contracted, or the abode of frogs, a fetus, or an army of soldiers; that his legs are transformed into glass or ice; that his whole body has assumed the shape of a teapot, or the magnitude of a hippopotamus. It is often a precursor of melancholia, as in the case of Cowper the poet, and other kinds of alienation; but it must likewise be regarded as a distinct and independent affection, traceable, generally, to dyspepsia, or disorder of the digestive and assimilative apparatus. It is probable that shades and degrees of this malady may constitute those links which connect partially healthy from absolutely unsound minds. In females, there are often added to the phenomena already described many of the symptoms of hysteria and great impressionability, and even convulsive affections; there is likewise encountered the simulation of diseases, the tendency to deceive others after having deceived themselves into the belief that they are invalids, and laboring under grievous and incurable disorders. They crave sympathy and support, as subject to affections of the spine, the joints, the lungs. They abstain from food, or devour inedible and disgusting substances; they writhe in what appears excruciating pain, and they voluntarily sustain great suffering during the treatment of their fancied ailments. A patient of Dr. Page, Carlisle, underwent amputation of the finger, wrist, forearm, and ultimately of the arm, in order to be relieved of sores which she produced. Certain of the maladies which are pretended, or feared, or fancied, appear to be called into existence under the morbid influence of volition: and there are strong grounds for believing that the concentration of attention upon a particular function, not merely interferes with its exercise, but disturbs the physical condition, and leads to degeneration of the tissue of the organ with which it is connected by capillary congestion, or evolution of nerve-force.—Falret, *De l'Hypochondrie et du Suicide* (1822); Andrew Combe, On Hypochondriasis, *Phrenological Journal*, vol. iii. p. 51; Cheyne, *The English Malady* (1733); Arnold, *Observations on Nature, Kinds, etc., of Insanity* (1782).

HYPODERMIC INJECTIONS, medicines introduced with a syringe beneath the skin. This method is often preferable to that of giving them by the mouth. The

stomach is sometimes in a condition which will not bear the presence of drugs, particularly narcotics, and these are the agents which are most frequently administered hypodermically. A small graduated glass syringe armed with a silver point, cut off obliquely so that its sharpened extremity may easily be made to pierce the skin, is used. The medicine may be thrown in just beneath the skin, but the point of the syringe is often thrust into the body of a muscle. The wounding of blood-vessels or nerves should be carefully avoided, and therefore the operation should never be undertaken except by a physician or an anatomist. Local pains may generally be more successfully treated in this manner than by the common method. In some cases an anæsthetic may, however, be preferable. It is usual to make a special preparation of the drug which is to be introduced. Morphia may be given in the form of sulphate, but some physicians prepare an acetate, according to directions given in the dispensatories. The syringe must be completely filled when used, otherwise the introduction of an air-bubble into a vein might be attended by danger, and if only thrown into the cellular tissue may cause inflammation and abscess. Other medicines than opiates are sometimes used, but they should all be used with caution. Habitual narcotization by means of hypodermic injections is as productive of a habit of opium taking as swallowing it, and physicians are often meeting with patients who will complain of pain at every visit, and beg for the use of the syringe.

HYP'OGENE (Gr. *formed beneath*), a geological term proposed by Lyell as a substitute for what is often called primary. He considered the latter term often inappropriate, because many granites are evidently of more recent formation than some secondary rocks. See GEOLOGY.

HYPOPHOS'PHITES, salts of hypophosphorous acid. The term is generally used in reference to certain medicinal salts. These are chiefly the hypophosphites of soda, potash, lime, ammonia, and iron, and more recently that of quinia, although this latter has not gained admittance into the pharmacopœias. The first four were proposed as specifics for pulmonary consumption, but although they have been used with some advantage in this disease, and in affections of the blood and of the digestive organs, they have failed to cure consumption. The hypophosphites of soda and lime are sometimes used in cases of debility, especially that depending upon prolonged lactation, but they need to be supplemented by ferruginous and other tonics.

HYPOSUL'PHITES, salts of hyposulphurous acid with bases. The most important are the hyposulphites of sodium, calcium, and sodium and silver. The last named double salt has recently been used as a topical application in place of nitrate of silver, than which it is more mild in its action. The hyposulphite of calcium has recently been used as a substitute for the sodium salt, or in similar diseases; but the latter substance, the hyposulphite of sodium, is the salt best known of all, and is used in the arts as well as in medicine. Among other methods, it may be prepared by digesting a solution of sulphite of sodium with flowers of sulphur, at a temperature somewhat below ebullition. When carefully prepared, it exists in large colorless crystals, having a mild, saline, sulphurous taste, very soluble in water, but insoluble in alcohol. It has the property of dissolving the chloride, bromide, and iodide of silver, and is used by photographers to dissolve away the silver compound which remains undecomposed upon the plate after its exposure in the camera. It is also used in chemical analysis to separate baryta from strontia in solutions of their salts. There are some very delicate tests for this salt; one of the most delicate is iodide of starch. The blue color which is produced by the suspension of almost infinitesimal quantities of this compound, is discharged by the addition of merely a trace of hyposulphite of sodium. Another test, recently discovered by Mr. M. Carey Lea, is ruthenium: an ammoniated solution of a salt of this metal, when boiled with hyposulphite of soda, turns to a rose-color, and then to a very rich carmine, which in strong solutions becomes almost black. The strong solution diluted produces various shades of color, rivaling aniline. In consequence of the power possessed by hyposulphite of sodium of destroying ferment organisms, it has been used as a remedy in zymotic diseases at the suggestion of Dr. Polli, of Milan; and reports from various quarters are that its use has been successful. Dr. Baxter, of Moscow, Iowa, reports having employed it in more than 100 cases of intermittent and remittent fever, without one failure. Dr. Corwin, U.S.N., in the treatment of small-pox on ship at Yokohama, reports its use with good results. The dose is from 10 to 20 grains three times a day, dissolved in a few ounces of water. It may be used as a lotion in skin-diseases in the proportion of a dram to a fluid ounce of water. See SULPHUR.

HYPOS'TASIS (Gr. *hypostasis*, subsistence), the term employed by Greek theological writers to designate the distinct subsistence of the three persons of the Trinity. Originally, the meaning of the word was unsettled. It was used by the fathers of the council of Nice, in the sense of *ousia*, essence or substance, and this confusion of phraseology supplied the most formidable weapon to the semi-Arians in the memorable Homoousian (q.v.) controversy. The use of the word hypostasis, however, was settled at a synod held by Athanasius in 357, in which it was fully distinguished from *ousia*, and explained as synonymous with *prosopon*, which the Latins rendered by *persona*, person. From this time, the word was adopted into the theological language of the Latin church, in which it is used indiscriminately with *persona*.

HYPOSTAT'IC UNION (Gr. *hypostasis*, person), a union of natures or substances so intimate as to constitute one undivided person. The term is used to describe the mysterious union of the divine and human natures in Christ, in virtue whereof, while each nature is complete, even after union, yet each merges its separate personality in the undivided person of the God-man, to which all the actions, whether divine or human, are ascribed. This form of expression was devised for the purpose of excluding the doctrine of a mere moral union held by Nestorius. See MONOPHYSITES, NESTORIANS, TRINITY.

HYPOT'ENUSE, or HYPOTH'ENUSE, the name of that side in a right-angled triangle which is opposite to the right angle. The well-known property of the hypotenuse, that the square described on it is equal to the sum of the squares described on the other two sides, is proved in the famous 47th proposition of the first book of Euclid's *Elements*, and has, in the sixth book, been generalized into the following form: The figure described on the hypotenuse is equal to the similar figures described on the other two sides. It is said that the 47th proposition was discovered by Pythagoras, who was so overjoyed at his good fortune that he sacrificed a hecatomb to the Muses. Camerer, in his edition of Euclid, gives seventeen different demonstrations of this proposition.

HY'POTHEC, a term in the law of Scotland, but not used in England, to denote a lien or security over goods in respect of a debt due by the owner of the goods. Thus, a landlord has a hypothec over the furniture or crops of his tenant in respect of the current rent; so a law-agent or attorney has a hypothec over the title-deeds of his client in respect of his account or bill of costs. In England these rights are called liens, and are not so liberally allowed. See Paterson's *Comp. of E. and S. Law*, s. 594. There is also a hypothec in favor of seamen over the freight in respect of their wages.

HYPOTHECA'TION is the pawning of a ship for necessaries, or to raise money in some critical emergency.

HYPOTHECA'TION indicates the right which a creditor has over something belonging to another, by which he may cause it to be sold to pay his claims. Conventional hypothecation is by agreement of the parties. General hypothecation implies about the same as an assignment for the benefit of creditors. Legal or tacit hypothecation is made without agreement between the parties. The public treasury has a lien on the property of public debtors, a landlord a lien on goods leased, and so mechanic's liens may be considered a form of hypothecation.

HYPOTH'ESIS. In endeavoring to explain natural phenomena, we have often to assume or imagine a cause, which, in the first instance, we do not know to be the real cause, but which may be established as such when we find that its consequences agree with the phenomenon to be explained. Every genuine theory was at one stage a mere conjecture, and became a true theory in consequence of being proved or verified by the proper methods. Thus, when it occurred to Newton that the force of gravity on the earth, as exemplified in falling bodies, might extend to the distance of the moon, and might be the power that compelled it to circle round the earth, instead of going off in a straight line through space, the suggestion was only an hypothesis, until such time as he was able to show that it accounted exactly for the facts, and then it became a theory.

A difference of opinion has arisen as to what constitutes a legitimate hypothesis, there being manifestly some necessary limits to the process of imagining possible causes. The case that has chiefly contributed to make this a question is the celebrated undulatory theory of light, a theory, or hypothesis rather, remarkable not only for the extent to which it explains the facts, but for having led to the discovery of new facts by way of inference from the theory itself. Notwithstanding all this amount of coincidence, the ethereal substance whose undulations are supposed to constitute light in its passage from the sun to the earth, is not known to have a real existence. It is an imaginary element, so happily conceived as to express with fidelity a series of extremely complicated phenomena. This was not the character of Newton's hypothesis as to the motion of the moon; the power supposed by him (the earth's gravity) was an actual or existing force, and all he did was to suggest that it extended as far as the moon. Accordingly, M. Auguste Comte and Mr. J. S. Mill have laid it down as the condition of a sound scientific hypothesis that the cause assigned to the phenomenon in question should be either a real cause, or capable of being ascertained to be a real cause, and that the liberty given to the scientific inquirer should be confined to imagining its operation in a particular sphere, and the law and amount of its operation, since both these could be verified by experiment and calculation. On the other hand, Dr. Whewell has contended that an amount of agreement with observed facts, such as has been exemplified by the undulatory hypothesis, is sufficient to establish not merely an hypothesis, but a theory, at least until such a time as some discordant facts arise, when the theory must be modified or abandoned. But whatever name be given to this class of suppositions, it is evident that they must be deemed inferior in scientific value to the other class of suppositions, where no cause or agent is assumed but what is actually known to exist, and where the only question is the presence of that agent in such manner and amount as to tally with the observed facts. Gravity, heat, electricity, magnetism, are established natural agents, and when we assume any one of these as the cause of some phenomena, we are on safe

ground so far, that if it be once shown that they are actually operative in the case we are dealing with, and that their calculated effect exactly coincides with the observed effect, the explanation is complete and final; no subsequent discovery can disturb a conclusion established in this way. But if we have to assume the very agency itself, or to imagine a power that we have no experience of, the coincidence between the laws of the assumed agency and the laws of the phenomena produces at best but a temporary or provisional evidence, which is liable to be superseded whenever a still better imagined machinery shall be brought forward. Thus, in the case of light, the first hypothesis, that of Newton himself, was a stream or shower of corpuscles; this gave way to the undulatory ether, whose merit lay in embracing the facts more closely; but we have no security against the ultimate preference of some third supposition which shall displace the second, as that did the first; while, perhaps, a day may come when an agency shall be proved to exist capable of explaining the phenomena. Even granting that we must sometimes assume an unknown agent (when an effect seems to be beyond the power of all the recognized forces), yet, in ordinary researches, it is considered a grave objection if the assumed agent be of such a subtle or occult nature, or so far removed from observation, that its existence does not admit of being proved. Such was the doctrine of the Cartesian vortices, and such are any hypotheses as to the shapes, sizes, and distances of the ultimate atoms of matter. Such also is the doctrine of nervous fluids, whereby the impulses of mind are supposed to be propagated between the brain and the other parts of the body.

HYPOXAN'THINE, a substance found in the spleen and muscles of the heart of man, and in the spleen and blood of the ox. It is a white crystalline powder, almost insoluble in cold hydrochloric acid, very slightly soluble in boiling alcohol, and requiring for solution in water 1090 equivalents of cold, or 180 of boiling water. Its solution has a neutral reaction.

HYPSILANTIS. See YPSILANTI.

HYPSOM'ETRY. See HEIGHTS, MEASUREMENT OF, *ante.*

HYRA'CEUM, a peculiar substance found in the crevices of the rocks of Table mountain, cape of Good Hope. It is one or more of the excrements of the cape Hyrax (*Hyrax capensis*). Hyraceum is a blackish-brown viscid material, not unlike soft pitch, having a strong and offensive taste, not unlike castoreum, for which it has been used as a substitute in medicine. At one time, so large a quantity was found as to suggest the idea of its being used as a manure, but the supply was soon exhausted, and only a small quantity is now imported to meet the demand of the curious pharmaceutist.

HYRACOTHE'RIUM, a genus of fossil pachydermata, belonging to the division perrysodactyla, the animals of which are characterized by having an odd number of toes. The genus was founded by Owen on the fragmentary remains of two species found in lower eocene strata; a third species from the same beds has been since described by him from more complete materials, under the name *pliolophus vulpiceps;* he considers it only a subgenus, and as we can see no characteristics to separate it generically from the other two, we place it here as a true hyracothere. The fossil was discovered in a nodule from the Roman cement bed of the London clay near Harwich. It is the most complete eocene mammalian fossil of the London clay. It consists of an entire skull and a portion of the rest of the skeleton, including the right humerus and femur, a great part of the left femur, the left tibia, and three metatarsal bones, apparently of the same foot, besides fragments of pelvis, ribs, and vertebræ. The head is 5 in. long, and 2 in. 2 lines broad; it is slender, tapering gradually from the zygomatic region to the muzzle; the upper outline is straight; the bony rim of the orbit is incomplete behind for about one-fifth of its circumference. The narrow skull and incomplete orbit ally it to the paleothere; the same form of orbit occurs also in the rhinoceros, and more exactly in the tapir. The straight contour of the skull, and the structure of the nasal aperture, show affinities with the horse and hyrax. The third molar of the upper jaw shows the structure of the teeth. The teeth, as well as the form of the lower jaw, tell plainly of the herbivorous character of the hyracothere. The bones of the leg exhibit ungulate affinities, and their form and proportions are between those of the hyrax and the tapir. The second species was founded on a mutilated cranium, rather larger than a hare's, found in the cliffs of London clay near Herne bay. It shows a skull very like the first species, though broader at the orbital region. The third molar tooth has a larger number of cones than the same tooth in the first species. The third species was founded on several teeth which belonged to a smaller animal than either of the others, found in the eocene sand underlying the Red Crag at Kyson, in Suffolk. The molar exhibits a structure similar to that of the others. From the same deposit were obtained two teeth belonging to a lower jaw, one of them, the third molar, still in its socket, and having a fragment of the jaw attached to it. These teeth were considered by Owen to belong to a quadrumanous animal, and were described by him as *macacus eocænus*, "at once the first terrestrial mammal which has been found in the London clay, and the first quadrumanous animal hitherto discovered in any country in tertiary strata so old as the eocene period." Since its publication, speculative geologists have made good service of this "monkey." Owen has, however, since stated (*Ann. Nat. Hist.*, Sept., 1862), that the two teeth belong to the third species of hyracothere.

HYRAX. See DAMAN.

HYRCA'NIA, an ancient district of Asia, bounded on the n. by the Caspian sea (sometimes called *Hyrcanum Mare*) and the Ochus river, on the e. and s. by the Sariphi mountains (now Elburz), which separated it from Parthia, and on the w. by Media. It corresponds with the modern Mazanderán and Asterabad. With the exception of the coast districts, and the valleys among the hills, which produced corn, oil, and wine, it was not a fertile region; dense forest prevailed, through which roamed multitudes of savage animals, the Hyrcanian tiger in particular being celebrated. The inhabitants were of the same stem as the Parthians, and were noted for their wild and rude character.

HYRCA'NUS, the name of two Jewish high-priests and princes of the Asmonean family.—1. JOANNES HYRCANUS, son of Simon Maccabeus, who ruled 136 to 106 B.C., was at first tributary to the Syrians; but on the death of Antiochus, made himself independent, subdued the Samaritans on the n., and forced the Idumæans on the s. to adopt the laws and customs of the Jews. He also concluded an alliance with the Romans, or rather confirmed that which his father Simon had previously made; built the strong fortress of Baris on the north-eastern angle of mount Moriah, and extended his territories almost to the ancient limits of the Davidian monarchy. He is also supposed to have founded the Sanhedrim (q.v.). Originally a Pharisee, he subsequently attached himself to the party of the Sadducees, who were anxious to keep on good terms with the Romans, and who discountenanced the turbulent religious patriotism of the Jewish masses. Hyrcanus was, comparatively speaking, a just and enlightened ruler, and the country enjoyed great prosperity during his reign. He left five sons, two of whom, Aristobulus and Alexander, governed with the title of king.—2. HYRCANUS II., son of Alexander, and grandson of the preceding, was a feeble prince. On the death of his father (78 B.C.), he was appointed high-priest by his mother, Alexandra, who ruled Judæa herself for the next nine years. After her death (69 B.C.), his younger brother, Aristobulus, a braver and more energetic man, seized the government, and forced Hyrcanus to withdraw into private life. Induced by the Idumæan, Antipater, and aided by Aretas, king of Arabia Petræa, he endeavored to win back his dominions, but was not successful until Pompey began to favor his cause. After some years of tumultuous fighting, Aristobulus was poisoned by the partisans of Ptolemy (49 B.C.), and Hyrcanus, who had for some time possessed, if he had not enjoyed, the dignity of high-priest and ethnarch, was now deprived of the latter of these offices, for which, in truth, he was wholly incompetent. Cæsar (47 B.C.), on account of the services rendered to him by Antipater, made the latter procurator of Judæa, and thus left in his hands all the real power, Hyrcanus busying himself only with the affairs of the priesthood and temple. Troubles, however, were in store for him. Antipater was assassinated, and Antigonus, son of Aristobulus, with the help of the Parthian king Orodes I., invaded the land, captured Hyrcanus by treachery, cut off his ears, and thus disqualified him for the office of high-priest, and carried him off to Seleucia on the Tigris. Some years later Herod, son of his old friend Antipater, obtained supreme power in Judæa, and invited the aged Hyrcanus home to Jerusalem. He was allowed to depart, and for some time lived in ease and comfort, but falling under suspicion of intriguing against Herod, was put to death (30 B.C.).

HYRTL, JOSEPH, a distinguished anatomist, was b. in 1811 at Eisenstadt, in Hungary, studied at Vienna, and early acquired eminence both as a scientific anatomist, and upon account of the extreme beauty of his anatomical preparations. He became professor of anatomy in Prague in 1837, and at Vienna in 1845. Whilst yet a student he enriched the anatomical museum of Vienna with many preparations. He has contributed not a little to the progress of comparative anatomy, especially that of fishes, and has made the anatomy of the ear a subject of very particular investigation. He has written many books and articles on the subjects above indicated, of which the two principal are *Lehrbuch der Anatomie des Menschen* (1847; 13th edit. 1875), and *Handbuch der Topographischen Anatomie* (1847; 6th edit. 1871). The former is a text-book in all German universities and has been translated into various languages. Hyrtl formed a museum of comparative anatomy at Vienna, and became rector of the university there, resigning office in 1874.

HYSSOP, *Hyssopus,* a genus of plants of the natural order *labiatæ,* distinguished by four strong diverging stamens, and a calyx with 15 ribs. The known species are few. The common hyssop (*H. officinalis*) is a native of the s. of Europe and the east. It is found on the Alps of Austria. It is a half-shrubby plant, about 1½ ft. high, the upper part of the stems quadrangular, leaves evergreen and lanceolate, the flowers in one-sided whorled racemes. The flowers are generally of a very beautiful blue. It has an agreeable aromatic odor. It has long been in cultivation for the sake of its leaves and young shoots, which are sometimes used for culinary purposes as a seasoning, but more generally in a dried state as a stomachic and carminative. A syrup made with them is a popular remedy for colds. The virtues of hyssop depend on a volatile oil.—It is very doubtful what plant is the hyssop of the Bible. It has been supposed to be some species of *phytolacca* (q.v.), as *P. acinosa,* a native of the Himalayas; but of late strong arguments have been advanced in favor of the common caper (q.v.).—HEDGE HYSSOP is *gratiola officinalis.* See GRATIOLA.

HYSTAS'PES, supposed to be the author of a work containing predictions of Christ and the future of his kingdom. Of his life nothing is known, and the book itself has disappeared. It is known only by mention made of it in later writers. It seems to have been a post-prophetic announcement of the coming and kingdom of the Savior.

HYSTE'RIA (so called from the Greek word *hystera*, the womb) is a disease which simulates so many other diseases, that it is not easy to describe it with the brevity which the limits of this work necessitate.

The hysterical fit or paroxysm—the most marked form or manifestation of the disorder—is almost, though not exclusively, confined to women, and chiefly to young women. In a severe case, the trunk and limbs are strongly convulsed; the patient struggles violently, retracting and extending her legs, and twisting her body with such force that the aid of three or four strong persons is often required to prevent a slight and apparently feeble girl from injuring herself or others. "The head," says Dr. Watson in his lectures, "is generally thrown backwards, and the throat projects; the face is flushed; the eyelids are closed and tremulous; the nostrils distended; the jaws often firmly shut; but there is no distortion of the countenance. If the hands are left at liberty, she will often strike her breast repeatedly and quickly, or carry her fingers to her throat, as if to remove some oppression there; or she will sometimes tear her hair, or rend her clothes, or attempt to bite those about her. After a short time this violent agitation is calmed; but the patient lies panting, and trembling, and starting at the slightest noise or the gentlest touch; or sometimes she remains motionless during the remission, with a fixed eye; till all at once the convulsive movements are renewed; and this alternation of spasm and quiet will go on for a space of time that varies considerably in different cases; and the whole attack frequently terminates in an explosion of tears, and sobs, and convulsive laughter.

In another less frequent form of the affection, the patient suddenly sinks down insensible and without convulsions; after remaining for some time in this state, with flushed cheeks, a turgid neck, and irregular breathing, she recovers consciousness, but remains for some time depressed in spirits and fatigued.

During the attack, especially in the first variety, the patient complains of uneasiness in the abdomen, and of a sensation as if a ball were rolling about, and rising first to the region of the stomach, and then to the throat, where she feels as if she were being choked. The abdomen is distended with wind, which moves with a loud rumbling sound along the intestinal canal, and is often discharged by eructation. Towards the close of the fit, but more commonly after it is over, a large quantity of pale limpid urine is discharged.

In many respects, this affection resembles epilepsy (q.v.). According to Dr. Marshall Hall, the most essential difference is this: that in hysteria, much as the larynx may be affected, it *is never* closed; while in epilepsy, it *is* closed. Hence, in the former we have heaving, sighing inspiration; and in the latter, violent, ineffectual efforts at expiration.

The hysterical fit varies in duration from a quarter of an hour or less to many hours.

The persons who suffer from hysteria are commonly young women in whom the process of menstruation is disordered, and who are either naturally feeble, or have been debilitated by disease or want; and in patients of this kind, the hysteria, or the hysterical tendency, is apt to show itself in mimicking so faithfully many of the most important diseases, that the physician has often great difficulty in determining the true nature of the case. Among the disorders that may be thus simulated by hysteria are, inflammation of the peritoneum (or peritonitis, q.v.), various forms of palsy, inflammation of the larynx (or laryngitis, q.v.), inability to swallow (or dysphagia), painful affection of the breast, disease of the hip and knee joints, and disease of the spine. Many of these cases of pseudo disease come to a sudden favorable termination under some strong mental or moral emotions. Those who are old enough to recollect the morbid religious excitement that prevailed at the time when Irving and his followers believed in the "unknown tongues," can hardly fail to remember the remarkable, or, as many regarded it, the miraculous cure of a young paralytic lady, who was made to believe that if, on a certain day, she prayed for recovery with sufficient faith, her prayer would be answered, and she would recover at once. She did so, and her palsy instantly disappeared. This case which was regarded by the believers in the movement as a direct answer to prayer, and as inaugurating a new era of miraculous cures, admits of easy and rational explanation by some psychologists. There are various instances on record where, in a similar way, an alarm of fire has instantly cured an hysterical paralysis that had lasted for years.

In the cases already noticed, the patient is not guilty of willfully deceiving the physician; but in other instances they are found to practice the most remarkable impositions, pretending by various frauds to be suffering from spitting of blood, from stone in the bladder, etc., or to be living without food of any kind.

Hysteria is a very troublesome affection to deal with, because it is very readily induced by example, or, as Dr. Watson terms it, is propagable by moral contagion. If, in a hospital ward or in a factory where many young women are congregated, one girl goes off in a fit, all the others who may happen to have a hysterical tendency will prob-

ably follow her example. In such cases, a decided order that the next girl who is attacked shall be treated with the actual cautery, or even with the cold affusion, will often have a marvelous effect in checking the spread of the disorder.

During the fit, the treatment to be adopted is to prevent the patient from injuring herself, to loosen her dress, and to admit an abundance of fresh cool air; to dash cold water upon the face and chest; and, if she can swallow, to administer a couple of ounces of the asafœtida mixture, or a drachm of the ammoniated tincture of valerian in a wine-glass of water. After the paroxysm is over, the patient should have an active purge, and the bowels should be kept properly open by aloetic aperients; and the shower-bath, preparations of iron, and tonic treatment generally should be adopted, and all abnormal bodily and mental excitement, such as late parties in hot rooms, novel-reading etc., carefully avoided.

HYSTEROT'OMY. See CÆSAREAN OPERATION, *ante*.

HYS'TRIX AND HYSTRI'CIDÆ. See PORCUPINE.

HYTHE (A.-S. *haven*), a parliamentary and municipal borough and market-t: of England, and one of the Cinque ports (q.v.), in the county of Kent, 14 m. s. of Canterbury, and about half a m. from the coast of the English channel, at the e. end of Romney Marsh. Lympne or Limne (the *portus lemanis* of the Romans), the ancient castle and harbor, about 2½ m. w. of Hythe, is now about two m. from the coast, the sea having gradually retired, first, to w. Hythe, and then to the present haven, which is still silting up. The town stands chiefly at the foot of a cliff, and consists of one main street, running parallel to the sea, with smaller ones branching off. It has an interesting church, partly Norman and partly early English. Under the chancel of the church is an extraordinary collection of human skulls and bones—many of the skulls having deep cuts in them—the age and origin of which are altogether uncertain. Hythe is now a place of great resort in the bathing season. The parliamentary borough of Hythe includes Folkstone, Sandgate, and some smaller places. Pop. of municipal borough, which includes w. Hythe, '71, 3,383. Hythe is about a m. from the Folkstone and Dover railway.

HYTHE SCHOOL OF MUSKETRY. See MUSKETRY, SCHOOL OF.

HYTÚ, or ITÚ, a t. in the province of San Paulo, Brazil; pop. 10,000. It is in a fertile region on the Feite river, and has a large trade in mules.

I

I, THE ninth letter in the alphabets of western Europe, was called by the Greeks *Iota*, after its Shemitic name (Heb. *Jod*), which signifies "hand." The oldest forms of the letter, as seen in the Phenecian and Samaritan, have a rude resemblance to a hand with three fingers; but by gradual simplification, the character came to be the smallest in the alphabet, and "iota" or "jot" is a synonym for a trifle. The original sound of the letter, and that which is considered its proper sound in all languages except English, is that given to Eng. *e* in *me;* with this power, it forms one of the fundamental vowels *i, a, u* (see A and LETTERS). What is called the long sound of *i* in Eng. is really the diphthong *ai* rapidly pronounced. The power that the vowel *i*, followed by another vowel, has of turning the preceding consonant into a sibilant, has been noticed in regard to the letter C (q.v.); further instances may be seen in such French words as *rage, singe,* from Lat. *rabies, simia*. In Lat. there was but one character for the vowel *i* and the semi-vowel now denoted by the character *j*. See J.

IABA'DIUS, a name given by Ptolemy to an immense island of the East Indies near Malacca. It abounded in grain and gold. It is thought by most investigators to be Java.

IAL'YSUS, an important Doric city of the island of Rhodes, very flourishing in the time of Homer, remains of whose former greatness are still found in the village of Ialisco. Of its origin nothing is known.

IAMBIC VERSE, a term applied in classic prosody, and sometimes in English, to verses consisting of the foot or meter called *iambus*, consisting of two syllables, of which the first is short, and the second long (⏑ –). Archilochus (q.v.) is the reputed inventor of iambic verse. The English language runs more easily and naturally in this meter than in any other. See METER, VERSE.

Thĕ stăg | ăt ēve | had drūnk | hĭs fill.
Lady of the Lake.

IAM'BLICHUS, the proper name of several persons in classical antiquity, as—1. A king of Emesa, who, in the civil war, took the part of Antony.—2. A Syrian freedman, who flourished at the end of the reign of Trajan and beginning of that of M. Aurelius (117–69 A.D.). He was instructed by a Babylonian in the language, manners, and literature of Babylon, and wrote the *Babylonica*, or loves of Rhodanes and Sinonis, in 16 or 39 books, which has been preserved by Photius, c. xciv., and Leo Allatius. It is

the oldest of the novels of antiquity which has reached the present day; but is not of any great merit either as to style or plot.—3. A philosopher who flourished under Constantine about 310 A.D., born of an illustrious and wealthy family at Chalcis, in Cœle-Syria, pupil of Anatolius and Porphyry, and of the Neo-Platonic school of Plotinus, whose doctrines he extended. Little is known of his life; but he was followed by a numerous school, who listened with enthusiasm and respect, and who thought that he was inspired, had intercourse with the gods, and could divine and perform miracles. This gave him immense credit. His doctrines were a syncretic mixture of Pythagorean and Platonic ideas, mixed with superstition and magic, and the supposed manifestation of God by ecstasies, and a communication with the spiritual world by ceremonies. One of his great works: On the Choice of Pythagoras (*Peri Aireseos Pythagorou*) consisted of 10 books, of which there remains the 1st, A Life of Pythagoras, filled with prodigies, and evidently written against Christianity. 2d, An Exhortation to Philosophy (*Protreptikoi Logoi eis Philosophian*), an ill-arranged introduction to Plato. 3d, On the Common Knowledge of Mathematics (*Peri Koines Mathematikes Epistemes*), full of fragments of Pythagoras, Philolaus, and Archytas. 4th, On the Arithmetical Introduction of Nicomachus. The 5th and 6th books are lost. The 7th, The Theology of Arithmetic (*Ta Theologoumena tes Arithmetikes*); the 8th, The History of Music; the 9th, Geometry; the 10th, On the Study of Heavenly Bodies. He also wrote a work on the Soul, commentaries on Plato and Aristotle, another on the complete Chaldean philosophy, another on Beginnings, and one on Sacred images, in which he affirmed that the gods resided in their statues. His celebrated work on the Mysteries (*Peri Musterión*) is, however, disputed; it is supposed by Meiners not to be written by Iamblichus; but is asserted by Tennemann to be the work of this author. It is drawn up as the answer of Abammon, a priest, to a letter addressed to his pupil, Anebo, by Porphyry. It contains many Egyptian doctrines, and esoterical explanations derived from the Hermetic books, the writings of Bitys and others, mixed with Pythagorean and Neo-Platonic ideas. The style of Iamblichus is not careful, and is inferior to Porphyry. Iamblichus is supposed to have died at Alexandria, 333 A.D.—Several other writers of this name are known, as a younger philosopher of the Neo-Platonic school, born at Apamea, and supposed to be a nephew of the preceding, praised by Libanius to Julian the apostate; another, son of Himerius, mentioned by the same author, and a physician at Constantinople.

Eudocia, *Violetum*, p. 244; Eunapius, *Vit. Philosoph.*, p. 20; Hebensbreit, *De Iamblicho* (Leip. 1744); Brucker, *Hist. Crit. Phil.*, ii. p. 260; *Iamblichus*, a Gale, fo (Ox. 1678).

IAN'THINA. See JANTHINA, *ante*.

IAP'ETUS, supposed by some to be the Japhet of the Bible. The Greek and Roman mythology considered him as the father of the human race. In classic mythology he is the son of Cœlus and Terra, and father of Atlas, Prometheus, and Epimetheus.

IBAR'RA, or SAN MIGUEL DE IBARRA, a t. of Ecuador, South America, in the department of Quito, and 60 m. n.e. of the t. of that name. It is situated on the northern base of the volcano of Imbabura, is well built, and carries on manufactures of wool and cotton. Pop. estimated at about 10,000.

IBE'RIA, a parish of Louisiana, lying on the gulf of Mexico, and intersected by Bayou Teche; 600 sq.m.; pop. '70, 9,042. Soil, fertile; surface, low and level; staple products: cotton, maize, and sugar-cane. There are forests of cypress and live-oak and beds of rock-salt. Cap., New Iberia.

IBE'RIA. See HISPANIA and GEORGIA.

IBE'RIS. See CANDYTUFT.

IBERVILLE, a parish of Louisiana, bounded w. by Atchafalaya bayou and e. by the Mississippi; 450 sq.m.; pop. '70, 12,347. The surface is low and level, and often inundated; land near the rivers is fertile. Staple products: cotton, maize, sugar, and molasses. Cap., Plaquemines.

IBERVILLE, co. of Quebec, Canada, e. of the river Richelieu; 190 sq.m.; pop. '70, 15,413; traversed by the Vermont Central, the Stanstead, Shefford, and Chambly railroads. Cap., Iberville.

IBERVILLE, PIERRE LE MOYNE, Sieur d'; 1661–1706; b. Montreal; one of five brothers distinguished in the French service. In 1686 he joined the expedition of De Troye from Canada against the English forts on Hudson's bay; in 1690 took part in the Indian and French massacre of the inhabitants of Schenectady; in 1694 captured Fort Nelson on Hudson's bay; in 1696 destroyed St. John's, Newfoundland, taking most of that province from the British; and in 1697 defeated them in naval fights in Hudson's bay. Sailing from Brest in 1698 with two frigates he reached the mouth of the Mississippi with his brother Bienville; fortified Biloxi, the first post on the Mississippi, and in 1700 ascended the river. In 1701, on account of the unhealthiness of the climate, he transferred the colony from Louisiana to Mobile, and began the settlement of Alabama. In 1702 he fortified Dauphin island, in Mobile bay; in 1706, with three ships, he captured the isle of Nevis, one of the Leeward group. He died at Havana, Cuba, July 9.

I'BEX, the ancient name of the bouquetin (q.v.), or steinbock of the Alps; and now, according to some zoologists, of a genus of the goat family, or subgenus of goat, having the horns flat, and marked with prominent transverse knots in front, whereas those of the true goats are compressed and keeled in front, and rounded behind. The species are all inhabitants of high mountainous regions. The ibex of the Caucasus and the ibex of the Pyrenees differ a little from the ibex of the Alps, and from one another, but the differences may perhaps be regarded as those of varieties rather than of species.

The conventional ibex represented in heraldry resembles the heraldic antelope in all respects, except that the horns are straight and serrated.

IBICUI', or IBICUY, an important affluent of the Uraguay (q.v.).

I'BIS, a genus of birds of the family *ardeidæ*, or, according to some ornithologists, of *scolopacidæ*, and perhaps to be regarded as a connecting link between them. The bill is long, slender, curved, thick at the base, the point rather obtuse, the upper mandible deeply grooved throughout its length. The face, and generally the greater part of the head, and sometimes even the neck, are destitute of feathers, at least in adult birds. The neck is long. The legs are rather long, naked above the tarsal joint, with three partially united toes in front, and one behind; the wings are moderately long; the tail is very short. The SACRED IBIS, or EGYPTIAN IBIS (*I. religiosa*), is an African bird, 2 ft. 6 in. in length, although the body is little larger than that of a common fowl. The GLOSSY IBIS (*I. falcinellus*) is a smaller species, also African, but migrating northwards into continental Europe, and occasionally seen in Britain. It is also a North American bird. Its habits resemble those of the sacred ibis. Its color is black, varied with reddish-brown, and exhibiting fine purple and green reflections. It has no loose pendent feathers.—The WHITE IBIS (*I. alba*), a species with pure white plumage, abounds on the coasts of Florida. Audubon saw multitudes on a low islet, and counted 47 nests on a single tree.—The SCARLET IBIS (*I. ruber*) is a tropical American species, remarkable for its brilliant plumage, which is scarlet, with a few patches of glossy black.—The STRAW-NECKED IBIS (*I.* or *geronticus spinicollis*) is a large Australian bird of fine plumage, remarkable for stiff naked yellow feather-shafts on the neck and throat.

The SACRED IBIS, one of the birds worshiped by the ancient Egyptians, and called by them *hab* or *hib*, and by the modern Egyptians *abu-Hannes* (i.e., father John), is a bird with long beak and legs, and a heart-shaped body, covered with black and white plumage. It was supposed, from the color of its feathers, to symbolize the light and shade of the moon, its body to represent the heart; its legs described a triangle, and with its beak it performed a medical operation; from all which esoterical ideas it was the avatar of the god Thoth or Hermes (see HERMES), who escaped in that shape the pursuit of Typhon, as the hawk was that of Ra, or Horus, the sun. Its feathers were supposed to scare, and even kill the crocodile. It appeared in Egypt at the rise, and disappeared at the inundation of the Nile, and was thought, at that time, to deliver Egypt from the winged and other serpents which came from Arabia in certain narrow passes. As it did not make its nest in Egypt it was thought to be self-engendering, and to lay eggs for a lunar month. According to some the basilisk was engendered by it. It was celebrated for its purity, and only drank from the purest water, and the most strict of the priesthood only drank of the pools where it had been seen; besides which, it was fabled to entertain the most invincible love of Egypt, and to die of self-starvation if transported elsewhere. Its flesh was thought to be incorruptible after death, and to kill it was punishable with death. Ibises were kept in the temples, and unmolested in the neighborhood of cities. After death they were mummied, and there is no animal of which so many remains have been found at Thebes, Memphis, Hermopolis Magna, or Eshmun, and at Ibiu or Ibeum, 14 m. n. of the latter place. They are made up into a conical shape, the wings flat, the legs bent back to the breast, the head placed on the left side, and the beak under the tail. They were prepared as other mummies, and wrapped up in linen bandages, which are sometimes plaited in patterns externally. At Thebes they are found in linen bandages only: at Hermopolis well preserved in wooden or stone boxes of oblong form, sometimes in form of the bird itself, or the god Thoth; at Memphis in conical sugar-loaf-shaped red earthen-ware jars, the tail downwards, the cover of convex form, cemented by lime. There appear to be two sorts of embalmed ibises—a smaller one of the size of a corncrake, very black, and the other black and white—the *ibis numenius*, or *ibis religiosa*. This last is usually found with its eggs, and with its insect food, the *pimelia pilosa*, *akis reflexa*, and portions of snakes, in the stomach. It is said to resemble the ibis of India rather than that of Africa. By the Jews it was held to be an unclean bird.—Wilkinson, *Manners and Customs*, v. 7, 217; Passolocgua, *Catalogue Raisonné*, p. 255; Pettigrew, *History of Mummies*, p. 205; *Horapollo*, i. c. 30, 36.

IBN-GANACH, ABULWALID MERWAN, or JONAH DJANAH, 995–1050; b. Cordova; a distinguished Jewish scholar. Removing to Saragossa he gave up the practice of medicine to devote himself to philological studies. His greatest work consists of two parts; the first chiefly a Hebrew grammar, and the second a Hebrew lexicon. The original is at Oxford, where it was of great service to Gesenius in the preparation of his thesaurus. Specimens of it, given by Gesenius and translated by Dr. Robinson, were published in the *American Biblical Repository*, 1833. The part which treats of Hebrew

grammar was published by Kirchheim (Frankfort-on-the-Main, 1856). "This gigantic work is the most important philological production in the Jewish literature of the middle ages. The mastery which it displays of the science of the Hebrew language in all its delicate points, the lucid manner in which it explains every grammatical difficulty, and its sound exegetical rules, have few parallels up to the present day." Ibn-Ganach was a proficient, also, in metaphysical studies, and composed a treatise on logic, in which he followed Aristotle. He strenuously opposed the speculations of Ibn-Gebirol and others of his day on the relation of God to the world as, in his view, dangerous to the maintenance of faith in the Scriptures.

IBRAHIM PASHA, the adopted son of Mohammed Ali, the viceroy of Egypt, was b. in 1789, and gave the first proofs of his gallantry and generalship in 1819, in quelling the insurrection of the Wahabis. He afterwards subdued Sennaar and Darfur. He invaded the Morea at the head of an Egyptian army in 1825, with the view of reducing it under the power of Mohammed Ali; but the intervention of the great powers in the affairs of Greece compelled him to abandon this enterprise in 1828. Mohammed Ali having conceived the design of adding Syria to his dominions, Ibrahim crossed the Egyptian border with an army in Oct., 1831, took Acre by storm, and quickly made himself master of the whole of Syria. A peace was concluded on May 4, 1833, the Turks not only consenting to give up Syria, but also making over Adana to Ibrahim personally, on a kind of lease. When war broke out again between Mohammed Ali and the sultan in 1839, Ibrahim was again successful, totally routing the Turks in the great battle of Nisib on June 24. The interference of the great powers eventually compelled him to relinquish all his Syrian conquests, and to return to Egypt. During his passage through the desert he suffered the most terrible hardships and losses, and the attempt to elevate Egypt to complete independence came to an end. In 1848, when the aged viceroy had sunk into absolute dotage, Ibrahim Pasha went to Constantinople, and was installed by the porte as viceroy of Egypt; but on Nov. 9, 1848, he died at Cairo. He was succeeded, not by any of his own children, but by Abbas Pasha, the favorite grandson of Mohammed Ali.

IBRAIL'. See BRAHILOV.

IB'YCUS, a Greek lyric poet, b. at Rhegium, Italy, in the 6th c. B.C.; lived mostly at Samos in the court of Polycrates. His writings are known only by fragments. A legend relates that when traveling he was waylaid by robbers near Corinth, and murdered. Looking up, mortally wounded, he saw a flock of cranes flying overhead, and implored them to avenge his death. The murderers went to Corinth, and in the theater saw the cranes hovering over the people. One of the murderers, in terror, cried out, "Behold the avengers of Ibycus." Inquiry led to discovery and punishment.

ICA, a t. of Peru, 170 m. s.s.w. from Lima, and connected by railway with Pisco, its port. It exports much wheat, maize, olive-oil, wine, and brandy.

ICARUS. See DÆDALUS, *ante.*

ICE is water in the solid form. It is specifically lighter than water which is just about to freeze, and therefore swims in it. Water, in becoming solid, expands about one-ninth of its volume or bulk. The formation of ice takes place generally at the surface of water. This is owing to the peculiarity, that when water has cooled down to within 7°.4 of freezing, it ceases to contract, as before, with increase of cold, and begins to expand until it freezes; which causes the coldest portions of the water to be always floating on the surface. In some circumstances, however, not very well explained, ice forms at the bottom of rivers, and is called ground-ice.

Water in ordinary cases freezes at the degree of heat marked 32° on Fahrenheit's thermometer, and 0° on the Centigrade and Reaumur's; but if it is kept perfectly still, it may be cooled to nearly 22° F. below freezing, and still remain liquid. The least shake, however, or the throwing in a solid body, makes a portion of it freeze instantly, and its temperature rises immediately to 32°. Sea-water, and salt water in general, freezes at a lower temperature than pure water; in doing which, part of the salt separates, and the ice, when melted, gives water that is fresher than the original The color of pure ice is deep blue, which is only descernible, however, when it is in large masses. It is best seen in the clefts of a glacier or an iceberg.

In the neighborhood of the poles, and on mountains of a certain height in all latitudes, there exist immense masses of permanent ice; and even in some districts of Siberia, where a kind of culture is practicable in summer, there are found at a certain depth below the surface of the earth strata of ice mingled with sand. In sinking a well at Yakutsk the soil was found frozen hard to the depth of 382 ft., and consisting in some parts entirely of ice. These permanent masses of ice must be classed with rocks and mountains, as among the solid constituents of the globe. In the lower regions of the torrid zone there is no ice, and in the temperate zones, it is a passing phenomenon. From the polar ice-fields and glaciers, which are always protruding themselves into the sea, great floating masses become detached, and form *icebergs*, floes, and drift-ice. These bergs or mountains of ice are sometimes more than 250 ft. above the sea-level. They present the appearance of dazzling white chalk-cliffs of the most fantastic shapes. Fresh fractures have a green or blue color. From the specific gravity it is calculated

that the volume of an iceberg below the water is eight times that of the protruding part. Icebergs, and floes or ice-fields, are often laden with pieces of rock and masses of stones and detritus, which they have brought with them from the coasts where they were formed, and which they often transport to a great distance towards the equator. These floating masses of ice are dangerous to navigation.

The hardness and strength of ice increase with the degree of cold. In the severe winter of 1740 a house was built of the ice of the Neva at St. Petersburg 50 ft. long, 16 wide, and 20 high, and the walls supported the roof, which was also of ice, without the least injury. Before it stood two ice-mortars and six ice-cannon, made on the turning-lathe, with carriages and wheels also of ice. The cannon were of the caliber of 6-pounders, but they were loaded with only ¼ lb. of powder, and with hemp-balls—on one occasion with iron. The thickness of the ice was only four inches, and yet it resisted the explosion.

About 24 years ago Faraday called attention to a remarkable property of ice, since (incorrectly) called regelation. He endeavored to account for the fact that two slabs of ice, with flat surfaces, placed in contact, unite into one mass when the temperature of the surrounding air is considerably *above* the freezing-point, by assuming that a small quantity of water, surrounded on every side by ice, has a natural tendency to become ice; and the fact that two blocks of ice placed in contact do not unite unless they are *moist* seems to bear out this idea. But J. Thomson gave a totally different explanation of this phenomenon. He showed that the capillary force of the film of water between the plates is sufficient to account for a very considerable pressure between them; so that from his point of view the phenomenon would be identical with the making of snowballs by pressure; and the formation, by a hydraulic press, of clear blocks from a mass of pounded ice, an observed fact, the explanation of which is to be found in the property of ice mentioned below. See *Proceedings of the Royal Society*, 1860–61. Faraday, taking up the question again, showed that the (so-called) regelation takes place in *water* as readily as in air, a fact quite inconsistent with the action of capillary forces. To this J. Thomson replied, showing, very ingeniously, that the capillary forces he at first assumed are not necessary to a complete explanation of the observed phenomena. See reference above.

Other views of the question are numerous, for instance, that of Persoz, adopted by Forbes, in which ice is considered as essentially colder than water, and as passing through a sort of viscous state before liquefying, as metals do during the process of melting. This idea, however, has not of late found much support; and it is probable that the true solution of the question is, as J. Thomson has lately pointed out, to be found in the analogy of the crystallization of salts from their aqueous solutions.

However that may be, there is no doubt about the following property of ice, theoretically predicted by J. Thomson from the experimental fact of its expanding in the act of freezing, and demonstrated by means of the piezometer by sir W. Thomson—viz., that the freezing-point of water, or the melting-point of ice, is *lowered by pressure;* and the brothers have, with singular ingenuity, applied this to the explanation of the motion of glaciers. That a mass of glacier-ice moves in its channel like a viscous fluid, was first completely established by Forbes. Thomson's explanation of this motion is of the following nature: In the immense mass of the glacier (even if it were homogeneous, much more so when full of cracks and fissures, as it always is), there are portions subjected to a much greater strain than others. The pressure to which they are subjected is such as corresponds to a melting-point considerably *below* the temperature of the mass—and therefore, at such points, the ice melts, the strain is relieved, and the whole mass is free for an instant to move nearly as a fluid would move in its place. But, the strains being thus for an instant removed, the temperature and pressure of the water are again consistent with freezing—the thin layer of water quickly solidifies, and then matters proceed as before. Thus, at every instant, the strains at different parts of the mass melt it at those places where they are greatest, and so produce the extraordinary phenomenon of a mass which may in common language be termed *solid*, and even *rigid*, slowly creeping down its rocky bed like a stream of tar or treacle.

Ice-Trade and Manufacture.—The trade in ice is now one of great and increasing importance. Ice has always been esteemed as a luxury in warm weather; and this early led to the storing of it in winter and preserving it for summer use. The Greeks, and afterwards the Romans, at first preserved snow, closely packed in deep underground cellars. Nero, at a later period, established ice-houses in Rome, similar to those in use in most European countries up to the present time. But these means were not enough to supply the luxurious Romans with ice for cooling beverages, and they actually established a trade in snow, which was brought to Rome from the summits of distant mountains.

The trade in ice in this country has, until lately, been very limited, having been chiefly confined to the supply required by a few of the first-class fishmongers and confectioners—the private residences of the more opulent families being furnished with ice-houses in which a sufficiency is kept for private use. But the North Americans have started a trade in this article in their own cities, which has extended to Europe and Asia, and has, in an incredibly short space of time, attained a surprising magnitude. The export of ice from America was commenced about 1820 by a merchant named Tudor, who sent ice from Boston to the West Indies. After persevering against many losses he

succeeded in establishing a trade with Calcutta, Madras, and Bombay; and now not only is it sent in vast quantities to those places, but also to Hong-Kong, Whampoa, and Batavia. About the year 1840 the Wenham lake ice company commenced sending ice to this country from Boston, which is the great American port for shipment of this material; and since then not only has there been a continually increasing demand, but the success of the company has been so great as to tempt others into the market. The supply for Great Britain, however, now comes almost wholly from Norway; 184,021 tons having been imported thence in 1876, of the value of £167,092, whilst only 10 tons were received from other countries. Fifteen or twenty years previous America had sent to Great Britain on an average 20,000 tons annually, costing as many thousand pounds.

In America the ice is chiefly collected in the neighborhood of Boston, Philadelphia, Baltimore, Washington, and New York, and the lakes which supply it form no small part of the property of those whose lands border thereon; these have all been carefully marked out, and the right secured, so that, when the winter comes, and the ice is formed, the harvest begins with great regularity. The ice is cleared from snow by means of an implement called the plane. An ice-plow, drawn by horses, and driven by a man riding upon it, is then made to cut deep parallel grooves in the ice, and these are again crossed by other grooves at right angles, so that the whole of the surface is deeply marked out into small squares, measuring a little more than 3 feet. A few of these square blocks being detached by hand-saws, the remainder are easily broken off with crowbars, and floated away to the ice-storehouses, which are usually built of wood, on the borders of the lake. Some of these are of vast dimensions, and contain vaults of great depth; the walls are double, and sometimes treble, being altogether as much as 4 ft. in thickness, and having hollow spaces between to render them less heat-conducting. The blocks of ice are covered up with sawdust, a layer being placed between each tier of blocks. Many of these ice-houses are made large enough to hold from 40,000 to 50,000 tons of ice. When fully stored a large quantity of dried marsh grass is trodden in upon the top, to the thickness of several feet, and the doors are then securely closed. The total value of the ice which is stored in America has been computed at £900,000, and if to this we add the ice-trade of Norway, Sweden, Russia, which, from the slight data we possess, is estimated at £600,000, we have the astounding fact that a value of one million and a half sterling is added to a comparatively small body of water by the mere act of freezing.

Notwithstanding the facilities for importing ice, there is, and always will be, a necessity for procuring it locally if possible. Hence there has been much talent brought to bear in devising means for artificial freezing. See FREEZING MIXTURES. But until recently the modes of producing ice artificially were too costly to be practically useful. The desideratum, however, may now be considered as supplied; for machines are constructed by Mr. Siebe of Lambeth capable of producing ten tons per day. Such a machine requires steam-power to work it, and its action consists in evaporating ether or any similarly volatile liquid *in vacuo*, and again condensing the vapor to liquid, so as to be used afresh. By this machine, 20° F. below zero (52° of cold) has been easily obtained, and such a machine is now regularly producing large quantities of ice nearly under the equator in Peru, where previously ice had never been seen; and others are used in India and at the Cape in the service of the government, for the use of the troops and hospitals. Another machine was first shown in the London exhibition of 1862 by the French firm of Carré & Co., which, from its extreme simplicity, and the fact that it can be adapted to the humblest kitchen, has led to its extensive application. The price is from £4 upwards; and as the volatile liquid is only the aqueous solution of ammonia, the cost of working it is very slight. The importance of low temperatures in many manufactures has lately increased the demand for freezing-machines, and they are now of great size and power. The machine-made ice has the same valuable quality that distinguishes the imported lake ice, viz., its perfect purity, so that pieces can be put into the drink that is to be cooled.

ICEBERG. See ICE.

ICELAND, an island in the northernmost part of the Atlantic, on the confines of the Arctic ocean; in n. lat. 63° 23′ to 66° 33′, and w. long. 13° 22′ to 24° 35, distant about 600 m. from Norway, and 250 from Greenland, 250 from the Faröe isles, and about 500 from the n. of Scotland. It belongs to the kingdom of Denmark. Its extent is about 39,207 sq.m.; its extreme length from e. to w. is upwards of 300 m., its greatest breadth from n. to s. about 200. Its coasts, particularly on the n. and w., are very much broken by bays or *fiords*. In some of the bays are numerous small islands. Iceland is in many respects one of the most interesting parts of the world. Its physical features are very remarkable, and not less so its history and the character of its inhabitants. It consists in great part of lofty mountains, many of which are active volcanoes; only certain level districts along the coasts, and a few dales, are habitable, or in any degree capable of cultivation, whilst even there scarcely a tree is to be seen, and the climate is unsuitable for grain. The interior of the island is almost entirely occupied with rugged tracts of naked lava and other volcanic products, vast ice-fields in many places connecting its high mountain summits, among which are prodigious glaciers, in some instances descending even to the coast, they and the torrents which gush from them

rendering communication between one inhabited spot and another very difficult and dangerous. Yet here has civilization been long established, and the people, necessarily very poor, have cultivated poetry and other departments of literature with great success.

The highest mountain in the island is Oeräfa Jökul, which attains a height of 6,426 ft. above the level of the sea. It is situated on the s.e., and is connected with a vast mountain mass, of which several of the summits are actively volcanic, no less than 3,000 sq.m. being perpetually covered with ice and snow at an elevation varying from 3,000 to above 6,000 ft., whilst all underneath seems to be full of either active or smoldering volcanic fire. The most celebrated volcano is Hecla (q.v.). Krafla is perhaps the most noted of a great group of active volcanoes in the n. of the island. The eruptions of Hecla have caused no little devastation, but still more terrible and destructive have been those of Skaptár Jökul and other volcanoes of the same mountain mass, which burst forth for the first time within the historic period in 1362. In repeated instances volcanic islets have been thrown up in the bays and near the coasts of Iceland, which have generally disappeared again within a short time. Connected with the volcanic fires are also hot springs in great number, some of which flow gently, and others, called *geysers* (q.v.), gush up at intervals and with ebullitions of great violence. Numerous hot springs may in many places be seen sending up their steam in a single little valley, and the Icelanders are accustomed to avail themselves of them for the washing of clothes and other purposes. The water of some is merely lukewarm, whilst that of others is boiling; some are pure, and some sulphureous. They are subject to great variations, and appear and dry up very suddenly. Earthquakes are frequent, and the island suffered very severely from this cause in 1755 and 1783. The winter is not generally more severe than that of Denmark, although more protracted, and it is rather the shortness of the summer and the insufficiency of summer heat, with the superabundance of moisture, than the severity of the winter, which is unfavorable to the growth of corn and plants of many other kinds. In the southern portions of Iceland the longest day lasts 20 hours; the shortest, 4 hours. In the northern districts the sun never sets for a whole week in midsummer, and in midwinter never rises above the horizon during an equally long period of time.

About 20,000 oxen, 30,000 horses, and 400,000 sheep constitute the chief part of the wealth of the inhabitants. The horses are small, but vigorous and active. They receive little attention from their owners, whose oxen require almost all the hay and other fodder they can store up for winter. Iceland ponies have now begun to be imported into Britain. Reindeer were introduced into Iceland by a public-spirited governor in 1770, and have become naturalized in the uninhabited tracts of the interior, where, however, their presence is of little importance. Seals abound on the coasts, where sea-fowls are also extremely numerous, and their flesh, eggs, and feathers are much sought after. Swans and other *anatidæ* frequent the lakes. The eider duck is plentiful on many parts of the coast, and its down is a principal article of commerce. Fish of many kinds are abundant on the coasts, salmon and trout in the rivers. The food of the people consists in great part of fish. The cod-fishery is extensively prosecuted by the French, from two to three hundred French vessels and about 7,000 seamen being employed in it, under the immediate patronage of the French government, which aims at thus training seamen for the navy. The salmon-fishery of some of the rivers has begun to be prosecuted for the supply of the London market. The herring-fishery has not hitherto received special attention, but vast shoals of herrings frequent the fiords. The most important agricultural operations are those of the hay-harvest. The seeds of the *melur*, or upright sea lyme grass (*elymus arenarius*), are gathered and used for making pottage and cakes, and are much relished; bread made of imported grain being rather a luxury in the houses of the common people. Meal made of Iceland moss (q.v.) is used in a variety of ways, and the lichen is gathered in large quantities both for home use and for exportation. Potatoes, turnips, kale and cabbage, spinach, parsley, radishes, mustard, cresses, etc., are produced in gardens. The mineral wealth of Iceland has only begun to be developed. In no part of the world is sulphur found in such abundance. Iron ore is also found. There is a peculiar kind of brown coal called *surtarbrand* (q.v.), which, along with driftwood, is much used for fuel on the northern and eastern coasts.

It is supposed that the population of Iceland was once 100,000, but it subsequently diminished. Since 1840, when it amounted to 57,094, a gradual increase has taken place, until in 1870 it had reached 69,763. The people, who are of Scandinavian origin, are distinguished for honesty, purity of morals, and a wonderful love of education. Notwithstanding their poverty and other adverse circumstances, it is rare to find an Icelander who cannot read and write. They belong to the Protestant church. The clergy are, like their parishioners, very poor; they are under one bishop. The Icelanders are strongly attached to their native country, and delight in the study of its history as set forth in ancient *sagas* and poems. Their language is the old Norwegian, preserved in almost its pristine purity. See SCANDINAVIAN LANGUAGES AND LITERATURE. They are rather a small race, and seldom attain to a great age. Scurvy was a very common disease, and cases of elephantiasis were frequent, probably owing in a great measure to the nature of their food, and still more to their miserably crowded and unventilated dwellings, which are mostly cottages of the humblest description, built of turf or of pieces of lava, the crevices stuffed with moss, and the roof formed of turf. The former of these diseases has now entirely disappeared, and the latter is

becoming very rare. The knitting of stockings and gloves is a common kind of domestic industry, and with the sale of skins, wool, feathers, eider-down, fish-oil, etc., enables the peasantry to procure a few articles of foreign produce. The chief imports are rye, barley, flour, coffee, liquors, tobacco, sugar, coal, iron, etc. Upwards of 40,000 Danish barrels of grain (of all kinds) are annually imported: also about 427,000 lbs. of coffee, 448,000 qts. of various liquors, 109,000 lbs. of tobacco, 457,000 lbs. of sugar, and 32,000 chaldrons of coal. The annual exports are valued at about £400,000, and consist of dried fish, wool, hosiery, tallow, train-oil, lard, salt meat, feathers, skins, and horses. The destruction of meadows by volcanic eruptions, and the interruption of fishing by drift-ice, have sometimes caused great distress. Since 1855 free-trade has been in force; 32 authorized trading-places have been opened, of which Reykiavik, with a pop. of 2,024, and situated at the head of a bay in the s.w. of the island, is the most important. Here the governor resides, and the *althing*, a kind of parliament, is held; here are a college, medical and theological schools, a public library of 10,000 volumes, a royal Icelandic society, and an observatory; and newspapers and Icelandic books are printed. There is regular steam-communication during summer with Leith and Copenhagen.

The authentic history of Iceland begins with the latter half of the 9th c., when emigrants from Norway settled here. The Landnama Book, however, one of the earliest of the records of the island, states that the Christian relics found here by the Norwegians on their arrival—as wooden crosses, etc.—had been erected previously by Irish settlers. However this may be, it is certain that the first authentic successful settlement of Iceland was made under Ingolf, a Norwegian, who, after a fruitless attempt on the s. coast in 870, succeeded in establishing himself at Reykiavik in 874. The changes introduced in Norway by Harald Haarfager caused many who could not endure them to betake themselves to other countries, and particularly to Iceland, all the habitable coast districts of which were occupied within sixty years, and the old Norwegian institutions were transferred to it unmodified. The government was at first, in the times of paganism, hierarchic and aristocratic; it became afterwards a kind of aristocratic republic. The althing met every summer in the valley of Thingvalla. Christianity was not established by law till 1000 A.D., and then not without much opposition. Schools were then founded, and two bishoprics in Holar and Skalholt.

The Icelanders were enterprising sailors in the early periods of their history, and discovered Greenland about the year 982, and a part of the American coast, which they called *Vineland*, about 990. They made voyages also to the south, visiting the furthest parts of the Mediterranean. The most flourishing period of Icelandic literature and commerce was from the middle of the 12th to the beginning of the 13th c., when, in consequence of domestic broils, Haco V. of Norway succeeded in reducing the whole island under his sway in 1262, and a declension began, which continued till a new impulse was given to the minds of men, here as elsewhere, by the reformation. When Norway was united to Denmark in 1380, Iceland shared its fate, but was not transferred along with Norway to a new allegiance in 1814. The Protestant religion was introduced in 1540, but not fully established till 1551. In the 17th c. the island suffered much from the ravages of Algerine pirates, who carried away many persons to slavery. In 1707 small-pox carried off 18,000 persons; in 1784–85 about 9,000 died of famine.—The althing, after it had subsisted for fully 900 years, was suppressed in the 19th c., but was reorganized in 1843. By the new constitution for Iceland of Jan., 1874, the althing has obtained legislative powers in all matters concerning Iceland. —See Von Troil, *Letters on Iceland*, 1772; sir George Mackenzie, *Travels in Iceland*, 1810; Henderson, *Journal of a Resident in Iceland*, 1818; C. S. Forbes, *Iceland, its Volcanoes, Geysers, and Glaciers*, 1860; S. Baring-Gould, *Iceland, its Scenes and Sagas*, 1863; capt. Richard F. Burton, *Ultima Thule: a Summer in Iceland*, 1875.

ICELAND MOSS, *Cetraria islandica*, a lichen found in all the northern parts of the world, and valuable on account of its nutritious and medicinal properties. It is collected as an article of commerce in Norway and Iceland. In very northern regions it grows even near the level of the sea; in more southern countries, it is found on mountains. It is not uncommon in the mountainous parts of Britain, although not turned to any economic account. In Carniola it is used for fattening cattle and pigs. It grows in extreme abundance in Iceland on tracts otherwise desert; and numerous parties migrate from great distances with horses, tents, and provisions, in the summer months, for the sole purpose of gathering it, as an article of commerce, and for food. In many places, this lichen thickly covers the whole surface of the ground, growing about 1½ to 4 in. high, and consisting of an almost erect *thallus* (q.v.). It is of a leathery and somewhat cartilaginous substance. When Iceland moss is used as an article of food, its bitterness is first partially removed by steeping in water, after which, in Iceland and other northern countries, it is sometimes pounded and made into bread; or it is prepared by boiling, the first water being rejected. It is often boiled with milk, making a kind of jelly, either with milk or water. It is an agreeable article of food, and very suitable for invalids. It contains about 80 per cent of a kind of starch called *lichen starch*, or *lichenin*, and owes its bitterness to an acid principle, *cetraric acid*.—An allied species, *cetraria nivalis*, growing in northern countries, possesses similar

properties. It is very abundant in some parts of Iceland, is much used for food, and is called *Mary's grass* by the Icelanders.

ICENI, a warlike tribe of ancient Britain, occupying, as is supposed, that part of the country which corresponds nearly with the present counties of Norfolk and Suffolk. Under their queen Boadicea they rebelled against the Romans.

ICE PLANT, *Mesembryanthemum* (q.v.) *crystallinum*, an annual herbaceous plant, a native of Africa and of the s. of Europe, remarkable for the watery vesicles (*papulæ*) with which its whole surface is covered, and which have the appearance of granules of ice, and sparkle in the same manner in the sun. It is common as a tender annual in our green-houses, the peculiarity from which it derives its name making it an object of interest. The seeds are used for food in the Madeira islands. The ashes supply barilla, and the plant is burned on this account in countries where it abounds.

ICH DIEN, translated to mean "I serve," the motto of the prince of Wales. According to one theory of its derivation, the phrase was employed by Edward I. on presenting his new-born son, Edward of Carnarvon, to the Welsh, using the expression in its Welsh signification—*Eich dyn*, "Behold the man." Another view attributes it to the occasion of the killing of John, king of Bohemia, by the black prince at Cressy, and asserts that the latter found the motto under the plume worn by the dead king, and assumed it to imply that "he served under the king his father."

ICHNEUMON, *Herpestes*, a genus of digitigrade carnivorous quadrupeds of the family *viverridæ* (q.v.), having a much elongated body, small head, sharp muzzle, rounded ears, and short legs. The species, which are pretty numerous, are natives of Africa and the warmer parts of Asia. One, the ANDALUSIAN ICHNEUMON (*H. widdringtonii*), occurs in the s. of Spain. They feed on small quadrupeds, reptiles, eggs, and insects. Some of them, particularly the EGYPTIAN ICHNEUMON (*H. ichneumon*) and the MANGOUSTE or MUNGUS (*H. griseus*) of India, have been greatly celebrated as destroyers of serpents and other noxious reptiles, many wonderful fables being superadded to the truth on this subject. The Egyptian ichneumon, the ichneumon of the ancients, is larger than a cat, gray, with black paws and muzzle, and a black tuft of diverging hairs at the end of the tail. It abounds in lower Egypt, but in upper Egypt it is comparatively rare. It often enters houses, and devours poultry and their eggs. With noiseless gliding motion it advances on serpents until it can suddenly seize them behind the head, where its long sharp teeth inflict a fatal wound. It scratches up the sand for the eggs of crocodiles, which it eats with great avidity. It was a sacred animal among the ancient Egyptians; the killing of it was forbidden: and individuals, for the maintenance of which funds were set apart, were objects of worship. The ichneumon is easily domesticated, and forms a cat-like attachment to the place of its residence. It is useful in keeping houses free of rats and other vermin. It is therefore not unfrequently domesticated in Egypt, as the mangouste also is in India. This species is rather smaller, of a lighter color, and has a pointed tail.

ICHNEUMON, a Linnæan genus of insects, now constituting a family or tribe, *ichneumonidæ*, of the order *hymenoptera*, section *terebrantia*. The *ichneumonidæ* are extremely numerous. Gravenhorst's *Ichneumonologia Europæa* describes nearly 1650 European species, and they are equally abundant in other parts of the world. Many of them are minute, others are large insects; a few of the tropical species are amongst the largest of insects. They have the abdomen united to the thorax by a pedicel, which is often very slender. The abdomen itself is slender, and the whole form attenuated. The antennæ are generally thread-like, composed of a great number of joints, and are kept in very constant vibration. The ovipositor in some is short; in some it is very long, much longer than the body of the insect, and inclosed in a kind of sheath formed of two parts, concave on their inner surface, from which it is disengaged when about to be used, the whole then often seeming as three threads proceeding from the extremity of the abdomen. All the *ichneumonidæ* deposit their eggs either in or on—generally in—the bodies, eggs, or larvæ of insects, or in spiders. Some of them deposit their eggs in aphides. They are thus extremely useful to the farmer and gardener. Particular species of *ichneumonidæ* are the natural enemies of particular kinds of other insects. Thus, *microgaster glomeratus* and *pimpla instigator* lay their eggs in the caterpillars of the cabbage butterfly. Some species deposit only one egg in the egg or larva which is destined to afford food to their own larva; others deposit a number of eggs together. Those which have a long ovipositor use it to reach eggs or larvæ under the bark of trees, in holes of wood, etc. The ichneumon larvæ generally consume only the fat of the larva on which they feed, which continues to subsist and so to sustain them till they are ready for transformation into pupæ. In their perfect state, the *ichneumonidæ* feed only on the juices of flowers. They are very often to be seen flying about umbelliferous flowers. The ichneumon larvæ are without feet. The pupæ of many are inclosed in silken cocoons.

ICHNOLOGY (Gr. science of footprints) is the name given to that section of paleontology which treats of the impressions made on mud or sand, now indurated into rock, by the animals of the period to which the rocks belong, or by meteoric or other transitory physical forces. The actual remains of the hard portions of the animals them-

selves are the materials on which chiefly rest our knowledge of the former inhabitants of the globe; but of many animals we know nothing more than the more or less distinct impressions made by them as they moved over the surface of a muddy shore. And in some beds, not only is the evidence of the shore-wave preserved in the ripple-mark, and the influence of the sun's heat exhibited in the superficial cracks, but frequently the passing hail-storm, or the sudden and heavy thunder-shower, has left its impress upon them, and this so perfectly, that it is not difficult to determine, from the form of the cup-like depression, whether or not the rain was accompanied by a breeze, for, by observing the amount of difference in the sides of the cup, and the position of the highest side, the direction of the gale and its velocity may be approximately determined. Though the force or body forming the impression has been removed immediately after it has made the pressure, yet in these prints the evidences of animal life and of the activity of physical forces have come down to us from the remotest periods.

The impressions occur almost invariably on rocks that have been deposited as mud; only in a few cases have they been noticed in sandstone. Sometimes the argillaceous deposit is a thin layer between two sandstone beds; it is then difficult to obtain a clear surface in the shale; but the details are carefully preserved in relief in the natural cast on the under surface of the superimposed sandstone. In this manner the footprints are preserved at Stourton in Cheshire.

The necessary conditions for the preservation of footprints seem to be either of the following. The silt-bed may have formed an extensive flat shore, uncovered by the tide at each ebbing. Whatever impressions were made on this plastic surface would be baked and hardened by the influence of the sun, if it remained for a sufficient time uncovered by the water; and when the tide again flowed, the hardened mud, resisting its influence, would receive another film of sediment, which would specially deposit itself in the depressions, and thus secure the permanence of the impressions. These influences would operate more powerfully on portions of the shore which were under water only at spring-tides. The impressions of numerous wading birds are preserved in this manner at the present day, on the plastic mud which covers the flat shore of the bay of Fundy, where the tide rises, it is said, as much as 70 feet. Both Gould and Lyell have given detailed accounts of the process as it goes on there. The other method is one independent of the sun's influence, where, on an ordinary muddy shore during the recession of the tide, the depresssions are filled up by blown sand, and the tide, on its return, flows over a level surface, on which it deposits a fresh layer of silt.

The study of ichnology carries us back to the remotest known period of animal life on the globe. The deposit from which has been obtained the fragment of the oldest known trilobite (palæopyge), contains the borings of certain worms, and impressions of rain-drops. In strata of the same period, but a little later, series of regularly recurring groups of markings are considered by Mr. Salter as having been produced by the sharp claws of crustacea in walking; while other sets he refers, with considerable show of probability, to the strokes of the bifurcate tail of an unknown crustacean as it swam through shallow water. From the American representatives of the same rocks (Potsdam sandstones), prof. Owen has described a number of impressions made apparently by different animals, to which he has given the generic name of protichnites. The slabs show that the animals made at each step 14, 16, or more impressions, They were most probably crustacea, furnished with three or four pairs of bifurcating limbs, like the modern king-crab. Similar impressions have been observed in the lower Silurian rocks of Eskdale in Scotland, and have been named *P. Scoticus*. The tracks of numerous annelids occur also in these rocks. They exhibit the impressions of the creatures as they moved along, or sometimes through, the soft mud, and they frequently terminate in a distinct impression of the form of the worm itself, produced perhaps by the dead body, although no trace of the body itself is preserved.

The footprints of a small reptile had been observed on the sandstone of a quarry near Elgin, which most probably belongs to the old red sandstone measures. In 1851 it was discovered that they were produced by a little reptile (*telerpeton Elginense*), whose remains were there found. And more recently, prof. Huxley has referred a different set of impressions to the remarkable fish-like reptile, stagonolepis, which he describes.

The coal measures of our own country and of Germany have disclosed the footprints of different reptiles.

The new red sandstone strata abound in footprints. It was the permian or lower division of this series that supplied, in 1828, the impressions which gave the first indication of animal life from such evidences to the mind of Dr. Duncan—a man who deserves to be remembered less for his works in natural history, important though they were, than for his eminent services to his country as the founder of savings-banks. The tracks he described occur on the layers of unctuous clay which separate the beds of sandstone in the quarries at Corncockle, Dumfriesshire; they frequently are clear and delicate, as at the moment when they were impressed, and are repeated bed after bed on the fresh tablets as they were prepared for their reception. From their number and direction, they seem to be the tracks of animals passing together across a tide-receded estuary, to some frequented ground periodically sought for food or pleasure. No animal remains whatever have been found associated with them; they seem, how-

ever, to belong to forms of tortoise. The pad of the foot was soft and smooth; the light impressions of the fore-foot were nearly obliterated by the hind-foot, which was furnished with four claws. Sir William Jardine, on whose property the Corncockle quarries are, has made these tracks the subject of a valuable and elaborate monograph.

In the triassic rocks the well-known foot-tracks of the labyrinthodon (q.v.) occur.

The earliest evidence of the existence of birds are the traces of their feet in the argillaceous sandstones of Connecticut, which are now known to be of the lower oolitic age. The structure of the tridactyle feet which produced these impressions exhibits the regular progression in the number of the toe-joints from the innermost to the outermost toe peculiar to birds, and they must be taken as evidencing the occurrence thus early of the class, although a considerable interval elapses before the first true fossil of a bird occurs; namely, the remarkable long-tailed bird from the upper oolite rocks of Solenhofen, recently described by prof. Owen. Immense tridactyle footprints have been known for many years in rocks of wealden age in the s.e. of England. At first they were supposed to be birds; but a more careful examination has shown them to belong to reptiles; and the discovery in the same strata of the perfect foot of a young iguanodon, measuring 21 in. in length, and furnished with three toes, which would form a print precisely similar to the tracks so long known, shows them to have been certainly produced by the iguanodon (q.v.).

ICHNOLOGY (*ante*). The fossil footprints, or ichnolites, of crustaceans are very numerous in America. Dr. Dawson has given much attention to this study. In observing the habits of the king crab he found that in walking over a sandy beach it makes marks like those called protichnites (see *ante*). In the sandstone beds which contain the protichnites are ladder-like impressions called climactichnites, and Dr. Dawson has shown that probably they are the marks made by the same crustacean, when swimming, which, when walking, produced the protichnites. The ichnolites found in the eocene of the Paris basin are numerous, the most notable being the trilobed footprints of several species of *paleotherium* (q.v.), and also those of *anoplotherium* (q.v.).

Great interest attaches to the footprints in the mesozoic rocks of the Connecticut valley from the fact that a majority of the tracks formerly supposed to have been made by birds were made, as shown by prof. Edward Hitchcock, by a huge batrachian, or frog-like animal. In his report published by the state of Massachusetts in 1836 he states that he had found ichnolites in the new red sandstone in 38 localities. In all there were the footprints of no less than 119 species of animals, comprising quadrupeds, birds, saurians, batrachians, tortoises, fishes, crustaceans, insects, and worms. Some of the surfaces show ripple-marks, and others rain-drop marks. The collection of the Connecticut valley ichnolites is now in the museum of Amherst college, and comprises more than 8,000 distinct tracks. Ichnolites have since been found in the same formation in New Jersey, and in the lower triassic sandstones of Lancashire and Cheshire in England, and in Hildburghausen, Saxony. The European footprints somewhat resemble an impression of the human hand, and for a while were supposed to be the footprints of a quadruped called *cheirotherium*, belonging to the kangaroo family. It is now, however, thought that the tracks are those of a crocodilean called *labyrinthodon*.

ICHTHYODO'RULITE (Gr. fish-spear stone), the name given to fossil fish spines, that are not uncommon in stratified rocks. Plagiostomous fishes have their dorsal fin furnished in front with a strong bony spine. The fin is connected with the spine, and is elevated and depressed by its movement. It seems also to be employed by the fish as a defense against its larger foes. Some bony fishes have similar spines, as the stickle-backs, silurids, etc. The spines are most frequently unassociated with any fish remains, having belonged to plagiostomous fish, in which the spine is simply implanted in the flesh, and consequently would be speedily separated from the body of the fish when it began to decompose.

The earliest certain evidence of vertebrate animals is the spines of plagiostomous cartilaginous fishes which occur in the bone bed of the Ludlow rocks, the uppermost of the silurian deposits. Spines belonging apparently to three species have been found, they are small, compressed, slightly curved, and finely grooved lengthwise, and belong to the genus onchus. Along with them have been found petrified portions of tubercular and prickly skin, like the shagreen of the shark.

The old red sandstone has supplied such a variety of spines as to have afforded the materials for establishing fourteen genera, and in the coal measures they are more numerous, belonging to no less than twenty-one genera.

ICHTHYOL'OGY (Gr. *ichthys*, a fish; *logos*, a discourse), that branch of natural history which treats of fishes. Aristotle is the most ancient author having any claim to be noticed in a history of ichthyology, nor was this science much indebted to any other of the ancients. In modern times, it began to be cultivated, about the middle of the 16th c., by Belon, Rondelet, and Salviani. Towards the close of the 17th c. it made great progress through the labors of Willoughby and Ray; in the 18th c., through those of Artedi, Klein, Linné, Gronow, Brunich, Scopoli, and Bloch; in the beginning of the 19th c., through those of Cuvier and De la Cépède; whilst, more recently, Valenciennes, Müller, Agassiz, and Owen are eminent amongst many who have prosecuted the study of ichthyology with ardor and success. The name of Yarrell deserves to be particularly

mentioned for his work on British fishes. The earlier ichthyologists generally included the *cetacea* among fishes. Linné removed the *cetacea* to their proper place. He also placed the *cartilaginous fishes* with reptiles in his class *amphibia*, from which they have since been, by the common consent of naturalists, brought back to their place in the class of fishes. Linné's system of ichthyology is almost as artificial as his system of botany. It is founded on the relative positions of the pectoral and ventral fins, without reference to any important point of comparative anatomy or animal economy. Other ichthyologists, both before and since, have labored to discover a natural arrangement, to which the progress of comparative anatomy has greatly contributed, although success is still confessedly very imperfect. Even the system of Agassiz, founded on the external covering of fishes, is not wholly artificial, and is of very convenient application to fossil ichthyology.

ICHTHYOLOGY. See FISHES, VERTEBRATA, *ante*.

ICHTHYOSAURUS (Gr. fish-reptile), a remarkable genus of reptiles which inhabited the sea during the deposition of the secondary strata. Like the modern cetacea, their structure was modified to suit their aquatic life. The body was shaped like that of a fish, the limbs were developed into paddles, and the tail, long and lizard-like, was furnished, it is believed, with a fleshy fin, as in the dolphin, except that its position was vertical. The head was large, and produced into a long and pointed snout, resembling that of the crocodile, except that the orbit was much larger, and had the nostril placed close to it, as in the whale, and not near the end of the snout. The jaws were furnished with a large series of powerful conical teeth, lodged close together in a continuous groove, in which the divisions for sockets, which exist in the crocodile, were indicated by the vertical ridges on the maxillary bone. The teeth were hollow at the root, sheathing the young teeth, which gradually absorbed the base of the older ones, and, as they grew, pressed them forward, until they finally displaced them. The long and slender jaws were strengthened to resist any sudden shock by being formed of many thin bony plates, which produced light and elastic as well as strong jaws. The most remarkable feature in the head was the eye, which was not only very large—in some specimens measuring 13 in. in diameter—but was specially fitted to accommodate itself for vision in air or water, as well as for speedily altering the focal distance while pursuing its prey. The structure, which thus fitted the eye so remarkably to the wants of the animal, consists of a circle of 13 or more overlapping sclerotic bony plates surrounding the pupil, as in birds. This circle acted as a sort of self-adjusting telescope, and, accompanied by the extraordinary amount of light admitted by the large pupil, enabled the ichthyosaurus to discover its prey at great or little distances in the obscurity of the night, and in the depths of the sea. The neck was so short that the body was probably not in the least constricted behind the head. The backbone was fish like; each joint had both its surfaces hollow, making the whole column very flexible. The small size of the paddles compared with the body, and the stiffness of the short neck, seem to suggest that the tail must have been an important organ of motion. Prof. Owen is satisfied that it was furnished with a vertical tail, because the vertebræ are compressed vertically, and also because the tail is frequently found disarticulated a short distance from its extremity, as if the weight of the upright tail had caused it to fall when the animal had begun to decompose. The fish-like body, the four paddles, and especially the powerful tail, would make the ichthyosauri active in their movements; and consequently, with their predaceous habits, very dangerous enemies to the other animals that inhabited with them the secondary seas. That their principal food consisted of fishes, is evident from the masses of broken bones and scales of contemporary fishes that have been found under their ribs in the place where the stomach of the animal was situated.

The remains of ichthyosauri are peculiar to the secondary strata, occurring in the various members of the series from the lower lias to the chalk, but having their greatest development in the Lias and oolite. More than 30 species have been discovered; they differ from each other chiefly in the form of the head, some having a long and slender snout, like the gavial of the Ganges, while others had short and broad heads, more like the common crocodile.

The great repository for ichthyosaurian remains hitherto has been the lias at Lyme Regis.

ICHTHYOSIS, or FISH-SKIN DISEASE, is characterized by a hardened, thickened, rough, and almost horny state of the cuticle, which breaks into small, irregular, scale-like pieces, which do not readily exfoliate, but which, if removed, are speedily reproduced. The disease may affect almost the whole surface, or may be confined to a single part; and is most frequently, but not always, congenital. It is attended with no constitutional disturbance, and the general health is often very good. The disease is, however, extremely obstinate, and when congenital, may be considered as incurable.

The treatment consists in the frequent use of the warm or vapor bath, so as to soften the thickened epidermis and to facilitate its removal, and friction by means of a piece of flannel may be conjoined with the bath. The employment of sulphureous baths, such as those at Harrogate, has occasionally been found of temporary use; and the internal administration of tar, cod-liver oil, etc., sometimes gives relief.

ICICA, a genus of trees of the natural order *amyridaceæ*, having pinnate leaves with an odd terminal leaflet, and white flowers in panicled racemes: the flowers having a small 5-toothed calyx, 5 petals, 10 stamens, and a cup-shaped disk with 10 crenatures on the margin, the fruit a drupe.—*I. icicariba* yields the American elemi (q.v.).—*I. heterophylla*, a tree of Guiana, yields a yellow aromatic balsam, which long retains its fluidity, and is used as an application to wounds. The resinous seeds are very fragrant.—*I. heptaphylla* and *I. Guianensis*, also natives of Guiana, yield very fragrant balsams, which harden into a gray resin, used as incense in churches and for other purposes, and esteemed useful as a medicine in dysentery.—*I. altissima* is a tree 100 ft. high, a native of Guiana, of which the wood is known as *white cedar* and *red cedar*, and as *acuyori*, *Samaria*, *mara*, and *curana wood*, is used for furniture and house-carpentry and for canoes.

I'CICLES, in heraldry, are charges of the same shape as drops in the bearing called gutté (q.v.), but reversed. They have also been called clubs, locks of hair, and guttés reversed.

ICIL'IUS, the name of a plebeian family in Rome, which produced some of the most zealous defenders of the plebeian interest against the patricians. The name of one of them is associated with one of the most touching incidents in the legendary history of Rome. See APPIUS CLAUDIUS.

I'CO, a t. of Brazil, in the province of Ceara, on the Salgado, 210 m. n.w. of Parahiba. The greater part of the inhabitants are shopkeepers, who supply the interior with articles of European manufacture, receiving produce in return, which they send down to the coast. Pop. 6,000.

ICOD', or ICOD DE LOS VINOS, a small t. on the n.w. coast of Teneriffe, one of the Canaries (q.v.). Pop. about 5,500.

ICOLMKILL'. See IONA.

ICO'NIUM. See KONIEH.

ICONOCLASTS (Gr. *eikon*, image, and *klazo*, I break), the name used to designate those in the church, from the 8th c. downwards, who have been opposed to the use of sacred images—that is, of statues, pictures, and other sensible representations of sacred objects—or at least to the paying of religious honor or reverence to such representations. The iconoclast movement had its commencement in the eastern church. Opinion is divided as to the origin and antiquity of the practice of image-worship (q.v.) in the church; but it is certain that in the 6th and 7th centuries it prevailed extensively, especially in the eastern empire, and that practices existed in some churches which were a source of much suspicion, and even of positive offense. Many bishops interposed to correct these abuses; but the iconoclast movement, strictly so called, began with the imperial edict issued in 726 by the emperor Leo III., surnamed the Isaurian, forbidding the honors paid to sacred images, and even commanding the removal from the churches of all images, that of our Lord alone excepted. This was followed by another decree in 730, which prohibited, under pain of death, as sinful and idolatrous, all acts of reverence, public or private, to images, and directed that, wherever such images should be found, they should forthwith be removed or destroyed. The attempt to enforce this decree occasioned great agitation, especially in the Greek islands and in Italy. The popes Gregory II. and Gregory III. protested vehemently against it, repudiated the imputation of idolatry, and explained the nature of the honors to images for which they contended. Leo persevered, nevertheless, in his opposition, which was continued by his successor, Constantine, surnamed Copronymus. Under this emperor a council was held in Constantinople in 754, in which the iconoclast decrees were affirmed in their fullest extent, and Constantine's son, Leo IV., renewed, on his accession in 773, the enactments of his predecessors. Under the widow of Leo, the empress Irene, a council was held at Nice, 786 (see IMAGE-WORSHIP), in which these proceedings were condemned and revoked; but other succeeding emperors, Nicephorus (802–811), Leo the Armenian (813–820), Michael the stammerer, and Theophilus, returned, with greater or less severity, to the policy of the iconoclast emperors. As regards the Greek church, the controversy may be said to have been finally settled under the empress Theodora in a council held at Constantinople in 840, or at least by a subsequent one of 870. The modern usage of the Greek church permits pictures, but rejects graven or sculptured representations of sacred objects. Except in Italy, the iconoclast controversy created but little sensation in the western church until the movement in the time of Charlemagne and his successors, which will be noticed under IMAGE-WORSHIP.

In the modern church, the popular violences directed in Switzerland, Great Britain, and some parts of Germany, against crucifixes, images of saints, and other objects associated with what has been stigmatized as the idolatry of Rome, have sometimes been described under the name of iconoclasm.

ICTINUS, a contemporary of Pericles. He was the chief architect of the Parthenon of Athens, 438 B.C., the temple of Epicurius in Arcadia, and the Eleusinian temple.

ICY CAPE, a headland of North America, is in 71° n. lat., about the middle of that long reach of the arctic coast between cape Lisburne on the s.w., and cape North or

Point Barrow on the n.e. It was discovered by Cook in 1778, and was his furthest point n. of Behring's strait.

IDA, a high mountain range, in Asia Minor, extending from Phrygia through Mysia into Troas. The city of Troy was situated at its base. It is the scene of many ancient legends. The southern part of the range was called Gargarus, the highest peak of which is about 4,700 ft. above the sea. Here there was a temple of Cybele, who therefore was called the *Idæan Mother*. From Ida flow several famous streams, as the Granicus, Simois, and Scamander.—There is another Ida in Crete, extending from w. to e., and now called Psiloriti. On this Ida, according to an ancient legend, Zeus was educated.

IDA, a co. in w. Iowa; 432 sq.m.; pop. '70, 226. Its soil is very fertile. Staple products: grain, potatoes, and sorghum. Capital, New Ida.

IDAHO, a n.w. territory of the United States, bounded n. by British America, e. by Montana and Wyoming, s. by Utah and Nevada, and w. by Oregon and Washington. Area 86,294 sq. miles. The surface is generally elevated, and the soil capable of high cultivation. Agriculture, however, has been little prosecuted; and the main source of the wealth of the territory consists in its gold, silver, and other minerals. Pop. '70, 14,999. Capital, Boisé City. Organized as a territory in 1863, Idaho was afterwards diminished in area by the abstraction of Montana to form a separate territory.

IDAHO (*ante*), a mountainous territory of the United States on the Pacific slope of the Rocky mountains, embracing many of the sources of the Columbia river; between lat. 42° and 49° n., and lon. 111° and 117° 10′ w.; bounded n. by British Columbia, which it touches only by a narrow strip, w. by Oregon and Washington territory, e. by Montana and Wyoming territories, and s. by Utah and Nevada. The e. line is irregular, following most of the way the course of the Rocky and Bitter Root mountains, so that the breadth of the territory, which is nearly 300 m. on the s., is less than 50 m. on the north. The length of the territory from n. to s. is nearly 500 miles. Its area embraces 86,294 sq.m., or 55,228,160 acres, of which only 16,925,000 acres are suited for agriculture, and 5,000,000 for grazing; over 14,000,000 acres which are now sterile might be reclaimed by irrigation. The mountain, timber, and mineral lands cover an area of 33,900,000 acres; the lakes 575,000 acres. Its arable portions are chiefly found in the river valleys and around the lakes; and even many of the valleys, notably the upper valley of the Salmon river, lie at so great an elevation, and surrounded by such a breadth of lofty snow-capped mountains, that the season between severe frosts is too short to permit much development of agriculture.

The mountain system of Idaho is peculiar, and its central uplifts are too separate, extensive, and lofty to be ranked as mere spurs of the Rocky mountain chain. The Salmon river range, which occupies the central part of the territory, a portion of which, near the sources of that great river, is known as the Saw-tooth range, is one of the most picturesque and lofty ranges of America. It covers an area as large as the state of New Jersey. The Snake or Shoshone river valley encircles it e., s., and w., and the Salmon river, w. of Salmon City, on the north. The following large tributaries of the Snake river all have their sources within a few miles from the junction of lat. 44° with long. 114° 30′, viz.: the Salmon, flowing n.n.w.; the Wood river, flowing s.s.e.; the Little Wood, in the same direction; the Lost river, s.e.; the e. fork of the Salmon, n.e.; and the sources of the three forks of the Boisé river, s.w. It is thus seen that the streams radiate to nearly every point of the compass from this lofty central range, yet all flow into Snake river at last. The government not yet having made a survey of this part of the territory, no map yet published (1880) gives any correct impressions of the sources or directions of the streams which flow from it. The Salmon mountains, like the Alps, are apparently without system or parallelism, and broken into a score of disjointed ranges, through which streams flow in all directions, in tortuous valleys, with intricate exits and entrances. The Wood and Salmon rivers, however, divide these mountain masses into two nearly equal parts by their valleys; Idaho having, as above indicated, a generally n.n.w. direction. The point where the two valleys head is known as the Wood river pass; is nearly 9,000 ft. high, but quite practicable for the construction of either wagon or rail road; while both valleys, to within a few miles of the summit of the pass, are easy planes for roads. These valleys and this pass are therefore the natural passage-way into the heart of Idaho. A road is just completed up the Wind river valley to within a few miles of the summit of the pass, and will probably be continued over the pass and down the valley of the Salmon to the Yankee fork before this description reaches the eye of the reader. It is at the sources of the streams that flow into these two valleys that extensive discoveries of silver and lead quartz veins, and some gold, have recently been made. The loftier parts of these mountains are generally granite or gneiss, but limestone belts are frequent, especially in the Wind river valley, and outcrops of slaty rock are found in many places.

In the northern part of the territory the Bitter-root, Kootenay, Cœur d'Alêne, and Clearwater mountains may be considered as spurs of the Rocky mountain range, while the Bear river ranges in the s.e. part of the territory form connecting links between the main continental divide and the Wasatch range. The crests and summits of the Salmon river mountains, and those of the n.w. part of the territory, range from 10,000 to

13,000 ft. above the sea; those of the s.e. are somewhat lower. The most remarkable feature of Idaho connected with its mountain system is the vast lava bed which covers the whole of the territory on the s.e. and s. along the course of the Snake river; forming a desert 400 m. long, mostly on the n. side of the river, varying in width from 40 to 60 m., and exhibiting over a considerable part of that area the black and ragged character of a recent volcanic eruption. It is the eastern end of a vast volcanic belt extending westerly to the Pacific; and of the same character as the lava beds in which capt. Jack with his Indian warriors long evaded the U. S. troops in California. The volcanic craters from which all this sea of lava has been poured out are plainly indicated by the planes of the flows, though the craters themselves are generally inconspicuous among the mountains that bound the lava on the north. W.n.w from fort Hall and Blackfoot station, on the Utah and Northern railway, are the Three Buttes, known since the first migration to the Pacific coast as landmarks on the great emigrant route which traversed this lava field near them to reach the foot-hills of the Salmon river mountains. These buttes rise, isolated, out of the lava plain, and have been volcanoes. The middle one, however, was last to spread its molten streams on every side, as proved by the descending planes of lava. It is probable that the whole northerly side of this volcanic belt was dotted with craters when the lava deposit took place, but they are now recognizable in a few places only, where last in action. After covering the great plain the lava flowed backward into the mouths of the valleys between the foot-hills on the n., so that nearly all the streams that flow e. and s.e. are dammed by the lava, and sink into its porous masses, flowing under it, to reappear after a subterranean passage from 30 to 50 m. as springs and cascades issuing from the basaltic walls of Snake river. The most rugged portion of this desert lies near the foot-hills on its northern edge. On the line of its back-flow to these hills, and up their valleys, the old emigrant road was forced to make its tortuous windings to avoid the rough lava. The lower portions of the plain nearer the Snake river, either by reason of greater age and disintegration, or by alluvial deposits upon it, are covered with soil upon which the sage-brush flourishes, and which needs only irrigation to be productive of whatever crops its elevation above the sea will permit.

Rivers.—The Snake or Shoshone river, or Lewis fork of the Columbia, with its branches, drains all the territory except the far n. and the s.e. portions. The Bear river, which flows into Great Salt lake, drains and waters a portion of the territory that admits of considerable agricultural development. The Snake rises in the main Rocky mountain range in Wyoming, entering Idaho on a n.e. course, then comes to the s. and by an irregular semicircle flows s.w., w., n.w., and n., where it divides the territory from Oregon; and thence turns westward to join the Columbia. Steamers ascend from its mouth to Lewiston, and it is navigable also from the mouth of Powder river to Salmon falls, a distance of 200 miles. It traverses a course of 850 m. in Idaho alone. Its chief tributaries from the n. side, in the territory, are the Clearwater, the Salmon, the Weiser, the Payette, the Boisé, and the Malade or Wood rivers; from the s. the Owyhee river, and a large number of smaller streams. The river from its entrance into the territory down to the falls at its southern curve is generally deep, narrow, and rapid, and can be used to irrigate large areas of adjacent lands now desert for lack of water. Below the falls it cuts deep through beds of lava and rock. Three falls in the river deserve notice. The American falls have a perpendicular descent of 60 or 70 feet. The Shoshone falls are inferior only to those of the Niagara and the Yosemite. The river here is 600 ft. wide. Above the falls it is divided by five islands into six parts, and then, after flowing 400 yards further, it passes in an unbroken sheet over a precipice, making a perpendicular descent of 200 feet. At some seasons of the year the body of water is almost equal to that at Niagara. The surrounding scenery is magnificent. The Salmon falls, 45 m. below the Shoshone, are 20 ft. high. There are numerous other waterfalls in the territory, some of which are of greater height than those above named, though the body of water is smaller. The valleys of the tributary streams are from 3,000 to 6,000 ft. above the sea, and some of them are from 10 to 15 m. wide. The Salmon river drains a large part of the central mountains of Idaho, and flows from its source s. of lat. 44, first n.n.w., then turns due e., where it receives the Yankee fork, a small stream recently made famous by great mines, and after flowing about 50 m. e., runs n. and finally w. to the Snake. Its head-streams are numerous, and formed directly from the snows of lofty mountain ranges, so that the river is a considerable stream near its source, there flowing through a valley of rare beauty, though too elevated to have value as grazing or agricultural land. At every part of its course it is fed by mountain streams. The Boisé river is made by the junction of the North, Middle, and South forks, which flow s.w. from the Saw-tooth range of the Salmon-river mountains and drop down from their sources to valleys of lower level than those of other parts of the territory; so that the s.w. part of the territory and the valley of the Boisé river are the warmest, and most varied in agricultural products. Fruits and vegetables of all kinds grown in the northern states flourish there. The Weiser and Payette rivers are chiefly noted for having been the theater of some of the most successful gold placer diggings ever known. The Wood river, known where it enters the Snake as the Malade, flows southerly from sources in lat. 44° in the Salmon-river mountains. Where it issues from the mountains on the northern edge of the lava

plain its detritus widens into a plain of 20,000 or more acres 5,700 ft. above the sea, which the river might be made to irrigate. The river above this descends through a narrow valley by an easy plane from its source in the pass at the head of the Salmon river. The Lemhi, the most easterly tributary of the Salmon, joins it at Salmon city, and is fed by short streams directly from the main divide of the Rocky mountains. The Clearwater is the main stream in the northern part of the territory, also known for its gold-washings. Three long narrow lakes furnish a peculiar navigation for the extreme northern part of the territory. These are the *Cœur d'Aléne*, about 18 m. long and 2 m. wide, emptying by the Spokane river into the Columbia; lake *Pend d'Oreilles*, really a wide part of Clarke's fork of the Columbia river, about 30 m. long and 2 to 6 m. wide; and lake Kanisku, flowing into Clarke's fork from the mouth. These lakes are bordered by a country rich in timber, especially a large growth of red cedar.

The climate of Idaho is somewhat varied, though generally delightful during the summer and autumn. The winters in the high mountains are extremely cold, with deep snows; but in the lower valleys and plains cattle sometimes winter without shelter. In the w. part of the territory the temperature is not very different from that of central Illinois; in the e. portion it is more like that of the n. part of New England, while in the high valleys of the mountains snows rest till June. Idaho was organized as a territory by congress in 1863, but with an area more than three times as large as that embraced within its present boundaries, having included the whole of Montana and nearly all of Wyoming. It was a part of the Louisiana purchase of 1803, and formed successively a part of Oregon and Washington territories. It was first explored by Lewis and Clarke, at the beginning of the present c., previous to which time it is supposed that no white man ever set foot thereon. After that it was traversed only by hunters and trappers until 1852, when gold was discovered near the northern boundary. The total population of the territory in 1870 was 20,583, of whom 5,631 were Indians, 4,274 were Chinese, and 60 were negroes. There is no record of the population at an earlier date. Of the population forming the basis of representation (14,999), 12,184 were males, 2,815 females—7,114 native, and 7,885 foreign born. The number of families was 4,104, of dwellings 4,622. The principal tribes of Indians were the Nez Percés, 2,807 in number, living on a reservation of 1,344,000 acres in the northern portion of the territory; the Shoshones, numbering 516, and the Bannocks, 521, living on a reservation of 1,568,000 acres in the s.e. part of the territory, and about 2,000 of other tribes, on a reservation of 266,000 acres n. of that of the Nez Percés.

Mines and Mining.—Gold, silver and lead are found near the sources of nearly every river in Idaho. Gold was first discovered in 1852 on the *Pend d'Oreilles* river, but not in paying quantities till 1860, when it was washed with profit on the s. fork of Clearwater river. In 1862 valuable gold-bearing deposits were found in the streams that form the Boisé river; the following year, in the tributaries of the Owyhee river; and subsequently exceedingly rich "finds" were worked in the valleys of the Weiser and Payette. This region, better known as the Boisé basin, proved one of the richest placer gold-fields ever found. These and other valleys in the territory are estimated by J. Ross Brown in a report to the government to have produced prior to 1868 $45,000,000 of the precious metals, nearly all gold. Rossiter W. Raymond, who brings the estimate down to 1873 inclusive, gives the product of 1868, $7,000,000; 1869, $7,000,000; 1870, $6,000,000; 1871, $5,000,000; 1872, $2,695,870; 1873, $2,500,000: making upwards of $75,000,000 as the total product of the precious metals in Idaho down to 1874. A U. S. assay office was established at Boisé city, the capital, in 1872. From the time of the exhaustion of the gold-washings of western Idaho, the mountains of every part of the territory have been searched for silver- and gold-quartz mines. In the Owyhee valley and Boisé basin many silver-mines have been worked with profit since 1872, but the difficulty of getting provisions and machinery into the mountains on the n. side of the lava-belt has seriously impeded their profitable development. In 1875–76 very valuable silver- and gold-quartz ledges were discovered on the tributaries of the Salmon river s. w. of Salmon city, the most famous of which are on Yankee fork, where Bonanza city has sprung up. The Custer mine there is remarkable for exhibiting the greatest mass of ore on the surface ever discovered. On that mine alone $200,000 were expended in 1880 to complete and stock one stamp-mill. In 1878 rich surface-ores were found on the s. sources of the Salmon river in the Saw-tooth mountains, and mines are now being developed there. The excitement caused by that discovery led, the following year, to the exploration of all the mountains about the sources of the Salmon and Wood rivers, in which previous to that year the Indians had been feared. These explorations led to the discovery of a great number of valuable mines of silver and galena ores, especially in the tributaries of Wood river; to which wagon-roads are now (1880) being made, and which promise to secure the construction of a railway across the lava desert to the valley of the river. Four villages sprang up in those high valleys in 1880 where two years before no sound of white settler had ever been heard.

Vegetation.—The forests of Idaho are confined to the n.w. part, and to the sheltered valleys of the mountains. Noble pines, spruces, and cedars abound in the n. and in the upper valleys of the Salmon-river mountains. Trees of these species, large enough for any timber that is needed, are found here and there in all the high mountain valleys. The red cedar of Kootenay and Shoshone counties is of larger size and in greater abundance

than is found elsewhere in the world. In the Boisé basins, on the w. slope of the Saw-tooth range, groves of the lofty Oregon long-leaved pine abound, which attains a height of 120 to 170 ft., a diameter of 4 to 7 ft., and serves for saw-logs almost to the summit. On the e. side of the same mountain the Norway spruce and the red pine attain a diameter of 3 to 5 feet. Other pines and firs furnish an abundance of small timber there. The country e. of the Salmon and Wood rivers is meagerly timbered, and below an altitude of 6,000 ft., except the deciduous growth that fringes the streams, trees are rarely seen. Willows, poplars, and the ash-leaved maple are the principal trees at the streams. Compared with the eastern states, the vegetable growth of Idaho is extremely meager. Wild fruits are very rare in most parts of the territory. Cultivated fruits and vegetables are grown with profit in many places, but more in consequence of the high prices they command than the ease or certainty of production; though in the s.w. part there are valleys where the climate admits of a profitable culture at low prices. The Boise basin is exceptionally noted for its fruits and vegetables. For grains only a small portion of the territory is adapted, yet there are broad stretches of land on both sides of the Snake river and in the valleys of its tributaries where irrigation would produce the same results in making crops of wheat, oats, and rye as it has done in Utah; and there are small tracts here and there throughout the territory where these crops can be grown without irrigation.

Of grazing-lands there are considerable tracts in the aggregate, but so scattered among mountain valleys that only a settlement of the state by the development of its mines will make the small valleys valuable. All along the n. side of the lava-belt the foot-hills and the Camus prairies furnish the thousands of cattle that pass eastward over the old emigrant road enough to live on as they travel. It is estimated that 150,000 head of cattle passed along that road in 1880. This indicates a high value for grazing during the summer; but the snow-fall at the elevation of about 6,000 feet necessitates winter feed for cattle. Along the Snake river, on both sides, there are numerous spots and valleys of grazing-lands where winters are not severe enough to prevent cattle and horses from picking up a living for themselves. Herders and packers who use mules and horses in the northern mountains through the summer season withdraw to the valley of the Snake river to winter their stock. In the n. part of the territory it is not so much the severity of the winter as the depth of the snow and shortness of the summer season that makes stock-raising of little account there.

Climate.—There is but little rain-fall in any part of southern Idaho. Towards the center the lofty mountains command a heavy snow-fall during 8 months of the year, and rob the plains of the precipitation of rain which their elevated ranges arrest. In the n.e. part the rain- and snow-fall is more equally distributed between mountain and valley. The climate of Idaho is so dependent on the elevation of its different parts that one must name each part to be described. Along the Snake river, and northward from it to the foot-hills of the Salmon and Rocky mountains, is a dry area of almost torrid heat under the sun from May till Nov.; yet the nights are always cool, and the air healthy and invigorating. The same hot sunny days are found up the lower valleys among the mountains, but there the nights are still cooler, and the warm season begins later and closes earlier. On the mountain-crests the snow frequently lies all summer, and ice forms almost every night; but even at those heights in the autumn the soil is perfectly dry to within a few feet of the melting snow. The winters are quite variable both on the plains and in the mountains, the winter variations from one year to another being greater than the summer. The thermometrical and barometrical ranges in Idaho have not been recorded to an extent that warrants any deduction or furnishes any valuable tables of reference. At fort Hall, in the s.e. part of the state, 4,754 ft. above the sea, the barometric range in 1871 from June to Oct. was but $\frac{24}{100}$ of an inch; the mean temperature for June was 64.62° F.; of July, 70.44°; of Aug., 70.90°; of Sept., 57.29°; and of the first 18 days of Oct., 57.28°.

The wild animals of the territory include the grizzly, the cinnamon or bald-face, and the black bear, the mountain lion (a large species of panther), wolf, cayote, wildcat, raccoon, badger, fox, beaver, sable, mink, otter, skunk, gopher, squirrels, rabbit, buffalo or bison, elk, moose, mountain sheep, wild goat, and antelope. Yet of all this variety no one species abounds except in the Boisé basin. The birds are not very numerous nor of great variety; the different species of grouse being the most abundant of the game birds. Snakes, numerous in the lava belt, are rarely seen above an altitude of 6,000 feet. Many of the same species of fish are found as in the streams of the eastern states; but the variety is not so great. The great fish of the territory is the salmon, which comes up from the Columbia river in immense numbers to spawn in the Salmon and other rivers, where it attains great size, sometimes from 40 to 60 pounds. Bears stand on the margins of streams and lakes where they abound, and by a quick motion of the paw kill the salmon as they pass in the water below. Salmon fishing and packing is one of the considerable industries of the territory, and the name salmon-eater is a term of ridicule applied by miners to those who live by fishing. In a few of the interior lakes of the Saw-tooth range of mountains the red-fish is found. This is one of the rarest and perhaps the most beautiful fish in the world. Humboldt stated that in his time they were known to exist in but five lakes in the world. They have since been discovered in the Idaho lakes. It is a fish that reaches a weight of 4 or 6 lbs., but

usually about 3 pounds It is supposed to exist only where chlorine is a constituent of the water. Its anatomy and habits differ from those of any other fish. It comes to the creeks in Aug. and Sept. to spawn, and is believed to remain near the bottoms of the mountain lakes at other seasons. When these fish first appear the meat is much prized, being fat and of fine flavor; but later they become less eatable. They are caught and salted in considerable numbers in the lakes of the Saw-tooth range w. of the Salmon river.

Some interesting fossils have been found, embracing remains of the mastodon, elephant, and tapir families, of bears and monkeys, of crocodiles, alligators, and other saurians, and of genera allied to the horse. The records of the Hayden expedition are rich in details of the botany, geology, and zoology of the territory.

The census of 1870 showed 77,139 acres of farms, of which 26,603 were under tillage. The assessed value of the property for taxation in 1876 was $4,381,227. The taxes levied for the same year, $114,198. The debt of the territory was $127,993. In 1870 there were in the territory 101 manufacturing establishments, with a capital of $742,300, and disbursing in wages annually $112,372. The annual product of these establishments, which were mostly gold and silver smelting furnaces, was valued at $1,047,624. There was one national bank at Boisé city in 1870, with a capital of $100,000; there were also several private banks in the territory. The schools of Idaho, like those of all sparsely settled communities with a heterogeneous population, are feeble and inefficient, though no more so than might be expected. The whole number of children of school age in the territory in 1875 was 3,852; the number attending school, 2,093. In 1876 the number in attendance was 2,724. Receipts for school purposes in that year, $36,215.42; expenditures, $16,590.55. The reports, however, are far from complete. Some of the schools were flourishing, and there is no lack of an intelligent public spirit to make them good in time.

The territory has but one railway, the Utah and Northern, a narrow gauge, on its eastern border, entering via the Bear river valley, coming to the Snake river at Blackfoot, crossing it at Eagle rock, traversing the lava fields n. to Pleasant valley, and thence up the Rocky mountain divide into Montana. Nearly the entire line in Idaho was built in 1878–79; and the profits of business that accumulated upon it in its progress almost built the road. A branch to the Yellow Stone park is under construction from Pleasant valley on this road. The Utah and Northern railway is owned by the Union Pacific railway company. Surveys have been made from this road at Port Neuf river and from Blackfoot westward across the lava beds to the Wood river and thence to Boisé city; also from Ogden up to the Snake river, on several lines designed to try the route of the Snake river s. of the lava field for a road to Oregon. Some one of these routes will be chosen the coming year (1881) by the Union Pacific company, and work prosecuted on it. The Central Pacific company are also contemplating the construction of a branch from Kelton, or near it, across the lava plain to the mining camps of the Wood and Salmon valleys. The recent development of mines in the interior of Idaho has stimulated the construction of wagon roads and trails; but the territory is in its infancy in this kind of work and needs the help of the government to give access to its mountain heart by roads of a better character than the poor miners can make for themselves. A movement of great value to the miners in its mountain recesses has recently been made for the purpose of encouraging the making of toll trails for mules and horses, which can be made at slight expense at elevations on the mountain sides where wagon roads would cost more than the returns from them would warrant.

Government.—Boisé city is the capital. The governor and secretary of the state, the surveyor-general, U. S. district attorney and marshal, register of land-office, and receiver, are appointed for four years by the president; the comptroller, treasurer, and superintendent of public instruction, are elected. The legistature has a council or senate of 13 members, chosen for two years, and a house of representatives of 25 members, chosen for one year. The U. S. court for the territory consists of a chief justice, two associate judges, clerk, district attorney, and marshal. There is one delegate to congress. The territory is divided into ten counties.

IDAHO, a w. co. of Idaho territory, extending from Oregon to Montana. It is watered by the Little Salmon and other streams. Much of it is mountainous, but there are fertile valleys, especially the Payette valley, producing grain, grass, maize, and cattle. Game and fish abound. Pop. '70, 849.

IDA'LIUM, a promontory of Cyprus, on which was a famous temple of Venus, whence the goddess was sometimes called *Idalia*. The modern name is Dali or Dalin.

IDE, *Leuciscus idus*, a fish of the family *cyprinidæ*, of the same genus with the roach, dace, chub, etc. It is a native of the lakes of the northern parts of Europe, ascending rivers in April and May to spawn. The ide is one of those fishes which it seems both easy and desirable to introduce into British waters.

IDE, GEORGE BARTON, D.D.; 1806–72; b. Vt.; graduated at Middlebury college 1830, and was pastor of prominent Baptist churches in Albany, Boston, Philadelphia, and Springfield, Mass., 42 years. He was distinguished for eloquence and erudition. Several of his sermons were published.

IDEA. This word has borne very distinct meanings in the history of philosophy. Down to the 17th c., it had the signification given to it by Plato, and referred to the Platonic doctrine of eternal forms existing in the Divine mind, according to which the world and all sensible things were framed. Plato made a grand distinction between the *intelligible*, or what occupied the intellect, and the *sensible;* the one represented the eternal, the immutable, and the certain; the other, the mutable and fleeting part of the universe. The forms preceded the matter; the actual circles occurring in nature were produced from a pre-existing ideal circle holding a place in the Divine intelligence; the actual men were generated from an ideal man. The word was used in this sense in literature as well as in philosophy down to the 17th c., as in Spenser, Shakespeare, Hooker, and Milton. Thus in *Paradise Lost*—

> God saw his works were good,
> Answering his fair *idea.*

Sir W. Hamilton dates the change that came over the application of the word from the publication of Descartes's *Discourse on Method* in 1637, remarking, however, that in a treatise by David Buchanan, published at Paris the year before, the new meaning had been introduced. "The fortune of this word is curious. Employed by Plato to express the real forms of the intelligible world, in lofty contrast to the unreal images of the sensible, it was lowered by Descartes, who extended it to the objects of our consciousness in general. When, after Gassendi, the school of Condillac had analyzed our highest faculties into our lowest, the *idea* was still more deeply degraded from its high original. Like a fallen angel, it was relegated from the sphere of Divine intelligence to the atmosphere of human sense; till at last *ideologie* (more correctly idealogie), a word which could only *properly* suggest an *à priori* scheme, deducing our knowledge from the intellect, has in France become the name peculiarly distinctive of that philosophy of mind which exclusively derives our knowledge from the senses."—Hamilton's *Discussions*, p. 70.

In speaking of the mental representation of external things, Descartes, instead of employing the various terms *image*, *species*, *phantasm*, etc., which had been the words formerly in use for that particular signification, used the word idea. In this he was followed by other philosophers, as, for example, Locke, who states that he has adopted the word to stand for "whatever is the object of the understanding, when a man thinks." Thus the mental impression that we are supposed to have when thinking of the sun without seeing the actual object, is called our idea of the sun. The idea is thus in contrast with the sensation, or the feeling that we have when the senses are engaged directly or immediately upon the thing itself. The sensation is what constitutes the *thing*, the reality: the impression persisting after the thing has gone, and recoverable by mental causes without the original, is the idea. Although the word in this application may be so guarded as to lead to no bad consequences, Dr. Reid was of opinion that it gave countenance to the setting up of a new and fictitious element in the operations of the mind. This, however, raises the great question of metaphysics—namely, the exact nature of our knowledge of an external world. See PERCEPTION.

It is difficult to avoid the use of the word idea, and yet, owing to the looseness of its application, there is a danger of its not conveying a definite signification. We need a general word to express the contrast to sensation, or to actuality; and no better term has yet been found than idea, being what is common to memory and to imagination, and expressing the mind as not under the present impression of real objects, but as, by its own tenacity and associating powers, having those objects to all practical ends before its view. Thus, all our sensations, whether of sight, hearing, touch, taste, or smell, and all the feelings that we have in the exercise of our moving energies, become transformed into ideas when, without the real presence of the original agency, we can deal with them in the way of pursuit or avoidance, or can discriminate and compare them, nearly as if in their first condition as sensation. Sir W. Hamilton, in his *Lectures on Logic* (i. 126), has endeavored to avoid employing the word, but other writers on mental philosophy have freely adopted it in the above acceptation. See also GENERALIZATION and IMAGINATION.

IDEALISM (IDEA, *ante*), as the term is generally used, is that scheme of philosophy which, carried to its legitimate results as was done by bishop Berkeley, regards all external phenomena as having no existence apart from a thinking subject. Descartes and his followers taught that nature has given to the mind various simple ideas, with the capacity also of compounding, separating, associating, and comparing them. The tendency of this theory is towards skepticism concerning everything except the existence of ideas. If they be the only objects of thought, and have no existence except when the mind is conscious of them, then no object of thought can have a continued and permanent existence. Bishop Berkeley, evading this consequence in regard to the existence of mind and spirit, asserted it concerning the material world. He maintained that there is no such thing as matter in the universe; that sun and moon, earth and sea, our own bodies and those of our friends, being only ideas in the minds of those who think of them, have no existence when not objects of thought; and that the universe may be reduced to two categories—minds, and ideas in the mind. To this conclusion philosophers before him had led the way. Descartes taught that the existence of objects of sense is not self-evident, but must be proved by argument. Others tried to find

arguments that would prove it, but without entire success; all their reasoning being, in the opinion of many, sufficient only to show that the existence of external things was probable but not certain. Malebranche rested the question on the authority of revelation; but to this the reply was that revelation itself can come to men only through their senses. Berkeley thought that if his theory were admitted many difficulties would be solved, many intricate points made plain, and skepticism brought to an end. But the actual result of his system was very different. By seeming to throw distrust on the evidence of the senses and to take away the grounds of a belief which is both natural and universal, its tendency was to shake men's faith in the primary truths which are the basis of their knowledge and the guides of their conduct. Beginning where Berkeley began, Hume went much further, and left hardly one article of human faith unassailed. He denied the reality not only of the object perceived, but of the mind perceiving; and reduced all thinking existence to a succession of rapidly fleeting ideas, each one being known only at the instant of its manifestation to consciousness, and then fading away. He maintained that men do not know that any one thing depends on any other in the relation of an effect to its cause; and the conclusion at which his reasoning aimed was not the mere negation of this or that positive belief, but universal distrust of the human faculties as a means for the acquisition of knowledge. They contradict each other, he said, and leave nothing certain except that nothing can be known as certain.

Idealism has indeed its interwoven truth, but it is a truth misapprehended and perverted. There are impressions, inferences, and imaginations, mingling, naturally or inadvertently, lawfully or unlawfully, with all genuine knowledge. These the ideal philosophy confounds, instead of distinguishing them in theory as common sense does in practice. As a system its radical vice is that while it admits the reality of certain objects, as mind and spirit, it inconsistently maintains that certain other things, as those of the material universe, which the mind just as intuitively knows to be real, are not real. It commonly begins by declaring that external objects have no such reality as men generally suppose them to have; advancing, from this point, to the denial that they have any reality at all, it still makes pretensions to a realism founded, not on the external phenomenon, but on the internal idea. From this refuge also logical necessity drives it away and forces it to assert that *self* is not as it seems, or that it exists only as it is felt, or when it is felt, and that men cannot know whether there be objects before them or not, or whether there be an eye or a mind to perceive them. There is no way of avoiding blank skepticism except by standing up for the trustworthiness of all the original intuitions of the human mind and affirming that there is a reality whenever those intuitions, taken comprehensively, actually declare that there is. If the mind can trust the faculties God has given it, it does perceive matter objectively; that is, something extended and solid is the immediate object of touch and sight; and this something is not in itself an idea, but matter.

IDELER, CHRISTIAN LUDWIG, an eminent astronomer and chronologist, was b. Sept. 21, 1766, at Gross-Brese, near Perleberg, in Prussia, and, after holding various offices, received a professorship at the university of Berlin in 1821. He d. Aug. 10, 1846. Ideler's most important works are, *Historische Untersuchungen über die Astronomischen Beobachtungen der Alten* (Leip. 1806); *Untersuchung über den Ursprung und die Bedeutung der Sternnamen* (Berlin, 1809); *Handbuch der Mathematischen und Technischen Chronologie* (2 vols., Berlin, 1825–26), the last of which was the first work that presented a clear view of the reckoning of time among the ancients; and *Die Zeitrechnung der Chinesen* (Berlin, 1839).

IDEM SONANS, a term sometimes used in English law, where a mistake as to a surname is made in a legal document, to denote that the name used by a mistake was of a similar sound, in which case the mistake is generally treated as immaterial.

IDENTITY of person in point of law must often be proved in legal proceedings, as in proving a marriage, proving a pedigree, proving a thief, etc. The usual proof is the oath of some one who knew or was cognizant of the facts at both the times referred to. A favorite defense of thieves and persons accused of crime is that it is a case of mistaken identity, in which case the prisoner must generally establish an *alibi*—i. e., that he was in some other place at the time in question.

IDENTITY, CONTRADICTION, AND EXCLUDED MIDDLE. It has been common to look upon some truths as necessary, in opposition to others that, although certain to all intents and purposes, are not necessary, but *contingent*. Thus, it is considered a necessary truth, that two straight lines cannot inclose a space; that the less cannot include the greater, that a man cannot be in two places at the same time. On the other hand, it is not necessary that gold should be yellow, or water transparent; these facts, we conceive, might have been otherwise arranged. There has been much controversy as to this character of necessity that distinguishes some of our beliefs from others. (See NECESSITY.) The schoolmen laid down three principles, involving what they considered the widest generalizations of our necessary beliefs: these are the laws of identity, contradiction, and excluded middle.

The law of identity is expressed thus: "Whatever is, is;" a proposition justly considered as irresistible. If any objection lies against it, it is, that nothing appears to be got by affirming it. When we say that "Water freezes at 32°," there is a piece of new

information conveyed; by merely knowing water in its liquid state, we should not know that at 32° it became solid; the affirmation is something real. But when we say that "Water is water," there is the form of information, but nothing is conveyed; the proposition belongs to the class termed "identical." We merely reaffirm what is already affirmed. The law of identity can only mean that we are to adhere to the meaning of a word as once given; that is to say, we should be consistent in the use of terms. It is a law, not of things, but of the employment of language to denote things.

The law of contradiction is, that "the same attribute cannot be both affirmed and denied of the same subject;" or that a thing cannot be and not be at the same time. In other words, two affirmations that contradict each other cannot be both true. We cannot say both that the "Sun has risen," and the "Sun has not risen;" "Gold is heavy," and "Gold is not heavy." Here, also, one might suggest the remark, that the proposition is an identical one; for the use of the word "not" can only mean that the proposition to which it is coupled cannot be held along with the proposition to which it is not coupled. That if the affirmative be true the negative must be false, and if the negative be true the affirmative must be false, are but the same thing differently expressed. The word "not" is an abbreviation for what would otherwise be a more roundabout expression. Instead of saying: "I disbelieve and deny that gold is white," we say: "Gold is *not* white." So far, therefore, the principle of contradiction, like that of identity, is not a law of things, but of the use of language; implying simply, that when we have affirmed a fact in one form of words, we must, in varying our terms, adhere to the same affirmation.

But this remark does not exhaust the scope of the principle. It has already been observed (see CONDITIONED), that our knowledge can never be confined to one absolute property; in other words to know a thing, we must know something different from it. We cannot even be conscious of one unvarying impression; animals that live in total darkness are not conscious of the darkness, they would become so only in passing into light. It is true that we are constantly in the habit of mentioning a single property, and leaving out of account the related fact but for which the first would have no existence; we may talk of light without alluding to darkness. But it is not the less certain that the alternative circumstance, for the time suppressed, is a real part of the case; and there are many occasions, when our meaning cannot be fully imparted without actually quoting the alternative; and to be logically or formally complete, we ought at all times to state the two.

There are many qualities the very mention of which brings vividly before the mind an opposed couple: as, up, down; straight, crooked; desire; aversion; etc. But beyond these cases, it is a tenable assertion that every fact or property recognized by the human mind must be recognized with relation to some other fact or property, its contrast or opposite, but for which as an alternative, the mind would not have that opportunity of *transition* essential to consciousness itself. Take *redness*, which does not suggest to the mind an opposite in the same manifest form as in the above instances. If all light were red there would be no designation of redness; the only terms would be light and dark. But as there are varieties of light, that is, as we experience mental shocks or impressions by transitions occurring under the luminous agency, we are made alive to subordinate differences, which we mark as so many distinct properties. When white and red are presented to the eye in succession, there is imparted a shock of difference, developing an item of knowledge, which, to be fully expressed, would be "white-red." White would then mean the opposite of red, and red the opposite of white; to the affirmation, "Snow is white," there would correspond as an essential and inseparable part of the same fact, "Snow is not red." But as there are a great many transitions of color that make the mind sensible to difference, the mention of one color is attended with, not one simple denial, but many denials. We have red-green, red-yellow, red-blue, etc.; and, moreover, when these couples pass in succession before the view, we are further struck with the fact of *agreement* in the common effect "redness." Thus, the fact or property, "redness," is the name for the common element in certain couples, which element it affirms, while denying in each case the contrasting element; it is not-white, not-green, not-yellow, not-blue, and not every other color, which placed side by side with it made the mind alive to difference. When, by differences and agreements as now described, a class of colors is constituted, the mention of one is the denial of every other member of the class; and the denial of one is the mention of some other or others, provided we are keeping our attention confined to that class. Prof. de Morgan introduced into logic the phrase "universe of the proposition," to intimate the class of objects implied when an affirmation, with its corresponding denial, is given forth. Thus, "Such a thing is red," implies as the universe of the proposition the class of colors; "A rose smells sweet" is in the universe "odors."

Many other examples might be quoted in illustration of the general principle, and also to show that, in the case of ambiguity or uncertainty in the meaning of a positive term, the proper remedy is to demand an explicit statement of the quality, or qualities, denied. Thus, if a thing is spoken of as "beautiful," which contrast is intended? for there are several implied in the name. Is it "beautiful, not ugly or deformed," "not indifferent or insipid," "not sublime?" etc. The important function of *defining* terms is thus, in the last resort, to bring into open statement, what is usually left in the form

of a tacit understanding, the denial corresponding to each affirmation. See also CONDITIONED.

The principle of excluded middle is another form of the principle of contradiction, implying the same general fact, and resting on the same foundation. It is, that of two contradictories both cannot be false, or one must be true. Any given assertion must be *either* true or false; either the affirmative is true, or otherwise the negative is true, which means that the affirmative is false. "This house is either mine or not mine;" "Gold is yellow, gold is not yellow," cannot be both false, one must be true. There is no *middle course* in such an alternative. But on examination, it will appear that this principle does not hold in the same unqualified sense as the principle of contradiction; for the attribute affirmed or denied must be something intelligible and definite, as well as relevant to the subject in hand. We often say such a thing is neither big nor little, implying that there is a certain mean point that excludes the extremes, and yet those two terms are the negative of each other. In a word, it is an essential condition of the principle that the universe of the proposition should be distinctly understood and kept in view. If we say, "This is either red or not red," the alternative is indisputable within the universe "color," but not otherwise; the taste of an orange is neither red nor not red; if we jump over the boundaries of the class, the principle no longer holds good.

The three principles of identity, contradiction, and excluded middle, are usually talked of as necessities of the human mind, from which there is no escape. But we have just seen that in the case of the excluded middle, there are possible evasions; and even the principle of contradiction itself is flatly met by Hegel, who lays it down as a maxim of his philosophy that "being" and "not being" are the same, and deduces important inferences therefrom. All this should make us cautious in declaring any formula or any doctrine to be absolutely necessary, or imperative on the human mind.

IDES. See CALENDS.

IDIOCY is the non-development of the mental faculties. A dement is deprived of powers which he once possessed; an idiot never, or only imperfectly, possesses such powers. In certain cases, the human form appears scarcely to be animated by intelligence at all; it is a senseless, motionless mass, to which the special senses impart no intimation of an external world, and from which there emanate no manifestations of human love or passion, or perception. The degrees of deprivation are, however, very numerous and sharply defined, so as to suggest different modes of management and training, and different degrees of moral responsibility in the individuals. The general characteristics of the vast majority of idiots may be held to be diminutive stature, grotesque appearance, inactivity, uncleanly habits, gluttony, obtuse or acute sensibility, inability to regulate movements, to articulate, to count, degradation of propensities, and helplessness. The various degrees of their dependence upon others has been estimated thus: of 574—53 were as helpless as infants; 74 as children of two years old; 94 as children of seven years old; 138 could engage in simple work with some small profit, if carefully watched and directed; 179 could nearly earn their bread; and 36 could, under due discipline, maintain themselves. In this calculation imbeciles are included. The arrestment of the evolution of intelligence, in whole or in part, may commence and be consummated previous to birth, in consequence of moral impressions, or accidents, or diseases on the part of the mother; during infancy, from defective nutrition or injudicious management; and during childhood up to puberty, from scrofula, rickets, hydrocephalous, and from unwise interference with the faculties in process of growth. A large number of idiots are microcephalous, or present heads of very small dimensions; and though they decay and die at an early age, they are apparently healthy. But a much larger number are not merely examples of imperfect growth; they labor under positive disease and degeneration, and present symptoms either of constitutional taint, or of those specific affections, such as convulsions and paralysis, as are referred to the nervous structure.

The ameliorations which occasionally takes place under judicious treatment, and the educability of a few individuals within a certain range, have suggested to physicians and philanthropists the propriety of attempting to rouse, direct, and apply such powers as may exist. The first attempt to give regular instruction to idiots was made in the Bicêtre at Paris many years ago. A magnificent training-school, now numbering about 600 inmates, has been some time in operation at Earlswood, Reigate; and there is a similar institution at Larbert, Sterlingshire, while a smaller school exists at Baldoran, Forfarshire.—Sequin, *Traitement Moral, etc., des Idiots;* Art. "Idiotisme," *Dict. de Médecine;* Abbots, *Handbook of Idiocy;* Buckminster Brown, *Treatment and Cure of Cretins and Idiots.*

IDIOCY (*ante*). The great distinction between idiocy and that form of insanity called dementia is that the latter is acquired, comes on in an individual who has had rational faculties, and therefore has vestiges of previously formed ideas; while the brain of the idiot is a blank, and of a kind which can scarcely be made to receive an impression until some further organic development is effected. The demented person, as the name implies, has lost a part of his mind, but the idiot is in a state of amentia, a term which strictly applies not to the demented condition produced by disease or feebleness,

except when the dementia is complete. Want of organization, or defective development, is the cause of idiocy, and this defect is apt to be accompanied by dwarfishness, and more or less apparent malformation and grotesqueness, and the defects are often so great that little or no mental structure can be erected, very little more, indeed, than the simplest habits, and these to a great extent connected with the promptings of the senses. The causes of idiocy are various. Its elements are no doubt hereditary, that is to say, a course of conduct in a parent which tends to degeneration, such as excessive sensual indulgence of any kind, will tend to induce arrested development in offspring. Residence in certain localities, as the lower valleys of the Alps, appears to favor arrest of cerebral and bodily development—according to Virchow—in consequence of the great amount of lime drank with the water. The attempt to educate idiots commenced in the 17th c , with an experiment of St. Vincent de Paul at the priory of St. Lazarus. His efforts to teach idiots, though continued for many years, were not successful. In 1799 the celebrated Itard took a wild boy, found in the forests of Aveyron and attempted to teach him; and although the success in this particular case was slight, he believed that he had discovered methods and facts which would be of use in other cases. These he communicated to his pupil, Dr. Seguin, who, in 1838, opened a school for idiots in the hospital for incurables at Paris. He met with success enough to have the idiots at the Bicêtre sent to the hospital to be instructed, and in the course of three years he received the approval of the French academy. Dr. Seguin adopted a system involving the theory that idiocy was prolonged infancy. His practice, founded upon this, was to excite and continue the process of development. Of course a variable success attended the experiment. The art of effecting such development requires much knowledge, tact, and patience. Different kinds of idiots need different stimulants, physical and mental. Pure air, good nutritious food, exercise; in short, any treatment which is calculated to increase the bodily and mental functions will improve the idiot. Wherever his interest can be awakened there will be a mental stimulus, and as the tendency of development is toward a normal standard, more or less improvement must follow. Of course the same amount of care expended upon healthy and normal children would show much greater results; and the most that can be expected in the education of idiots is to make them as comfortable and as cheerful as circumstances will allow. It might indeed be possible, by continuing the education of idiots through many generations, to raise them to an approach to the normal primitive standard of manhood, but the difficulties would be great.

According to the census of 1870, which is the latest authority obtainable at the present time, Nov., 1880, the number of idiots in the United States was 24,477, distributed among the States as follows:

Alabama	721	Maryland	362	Rhode Island	123
Arkansas	289	Massachusetts	778	South Carolina	465
California	87	Michigan	613	Tennessee	1,091
Connecticut	341	Minnesota	134	Texas	451
Delaware	69	Mississippi	485	Vermont	325
Florida	100	Missouri	779	Virginia	1,130
Georgia	871	Nebraska	25	West Virginia	427
Illinois	1,244	New Hampshire	325	Wisconsin	560
Indiana	1,360	New Jersey	436	District of Columbia	50
Iowa	532	New York	2,486	New Mexico	46
Kansas	109	North Carolina	976	Utah	23
Kentucky	1,141	Ohio	2,328	Other Territories	15
Louisiana	286	Oregon	55		
Maine	628	Pennsylvania	2,250	Total	24,477

But this number falls below the reality, and for various reasons. Parents are often unwilling to admit or to believe that their children are idiots, and often present them to physicians and asylums for treatment for "strangeness of manner," etc. The degrees and forms of idiocy are also various, and not easily recognized by an unprofessional person; thus many escape being put in the list by the census taker. The number of idiots in England, Ireland, Scotland, and Wales was estimated according to the census of 1871 to be 39,452, but it has been thought by competent authorities to be over 50,000. In Switzerland the number of idiots is estimated to be about 4,000. See CRETINISM.

IDIOSYN'CRASY (Gr., a peculiar temperament), the name given to any constitutional peculiarity. Thus, there are persons who have a great dislike to particular kinds of foods, smells, sounds, etc., which to most persons are agreeable; and, on the other hand, a desire is sometimes manifested for things generally disliked. In particular individuals, again, an eruption of the skin will be caused by eating strawberries, or swooning by the smell of a rose, and that quite unconnected with any liking or disliking; and such effects are produced when the person is unaware of the cause. Idiosyncrasies also occur, in consequence of which certain medicines become inoperative, or certain poisons harmless. Idiosyncrasies are either permanent or temporary, sometimes arising from mere morbid conditions, and disappearing along with them.—The term is also employed to denote *mental*, as well as *physical* peculiarities.

IDOM'ENEUS, a Greek who succeeded his father, Deucalion, as ruler of Crete, called also Lyctius and Cnossius, from the Cretan towns Lyctus and Cnossus, of which he is

said to have been a native. He accompanied the Grecian fleet with 80 ships to the Trojan war, where he was distinguished for valor. It is said that, overtaken by a tempest on returning, he vowed to Neptune that if saved he would sacrifice to him the first living thing that met him on the Cretan shore. It was his son who appeared, and he fulfilled his vow, but for his cruelty was banished by his subjects. Sailing to Italy, he founded a city in Calabria, and built a temple to Minerva. From Calabria he went to Colophon, where he died.

IDOCRASE. See VESUVIAN.

IDOL (Gr. *eidōlon*, an image), **IDOLATRY** (worship [*latreia*] of images). By the name idol is meant an image intended to represent a divinity, and to be adored as such. The act of worshiping such an object as a divinity is called idolatry. Although the first principles of reason suggest to man's mind the idea of one supreme being, the source of all existing things, and the origin of all good (see GOD), yet the very earliest historical records, sacred and profane, teem with evidences of the errors into which men quickly fell through ignorance and passion, changing "the glory of the uncorruptible God into an image made like to corruptible man, and to birds, and four-footed beasts, and creeping things" (Rom. i. 23). To these images, as well as to the images of inanimate objects, or of the ideal powers or forces supposed to be embodied in such objects;—as the sun, the moon, the stars, air, water, fire, and other natural elements—divine honors were paid by most of the ancient nations; to which honors the name of idolatry has been given. Hence, as each of these corrupt worships had its own peculiar symbols, the idolatry of the ancient gentile religions may be reduced to four classes: 1. The idolatry of nature-worship, which was of two kinds—the first of inorganic nature, which consisted chiefly in *litholatry*, or the worship of stones or pillars, mentioned in Leviticus, xxvi., and in Numbers xxxiii. 52; the second of organic nature, or of the powers of nature, as *dendrolatry*, or the worship of trees—under which form were symbolized the productive or generative powers of nature, and to which the most modern investigators of Phenician antiquities trace the origin, as well of the grossly immoral worship of the *Ashtaroth* of the Phenicians, as of the phallic worship, which found its way, under various forms, through all the kindred races, both in the west and in the east. 2. The idolatry of animal worship, which we find as well in the (perhaps originally symbolical) worship of the sacred oxen, the crocodiles, and serpents among the Egyptians, as in that of the still more degrading forms of animal life which constituted the object of adoration with other nations. 3. A higher form of idolatry, which prevailed among the races of Chaldean origin, was *astrolatry*, or star-worship, which is often designated by the name of *sabæism*. There was one form of sabæism which cannot strictly be called idolatry, as it did not involve the use of idols, but addressed itself directly either to the heavenly bodies themselves, or to the element of fire, with which they were associated. But the same object of religious worship, coupled with the use of idolatrous representations, is found in the worship of Baal, of Moloch, and of Tammuz, the Phenician Adonis (Ezekiel, viii. 14). 4. The last form of idolatry, and that which prevailed in the later period of the ancient gentile religions, was *anthropolatry*, or the worship of representations of the human form. It is chiefly familiar to us through the mythology of Greece and Rome, but it also found a place in most of the other religious systems, in some of which the representations of the human form were variously modified, so as to symbolize those special attributes which form the peculiar objects of the worshipers' adoration. Of this there are many examples in the mythological representations of the Egyptians and of the Indians. In the Egyptian religion, indeed, and in the later Grecian, many of the idols were representations of pure abstractions, as of certain faculties or affections of the mind, of virtuous desires, or of evil passions. Nor can it be doubted, that among the more cultivated classes, there were individuals by whom these abstractions were fully understood, and by whom the crude idolatry of the multitude was regarded solely as a device adapted to their more gross and material conceptions.

The Jews, notwithstanding the many safeguards by which the belief of the one supreme being was protected in their religious system, were frequently seduced into the idolatrous worship of the gentile nations among which they were thrown. It is one of the most remarkable among the anomalies of the history of this singular people, that the great and radical purification of their faith in the unity of God dates from their protracted Babylonian captivity, from which time it was maintained, notwithstanding the effort of Antiochus Epiphanes to introduce the Greek idolatry (1 Macch. i.) down to the coming of our Lord. The idolatry into which the Jews fell at different periods was chiefly of the first and the third forms described above.

The idolatry of the savage tribes of the African and Oceanican races is for the most part of the class described under the head FETICHISM.

IDRIA, a small but important t. of Austria, in the crownland of Carniola, celebrated for its quicksilver mines (discovered in 1497), is situated in a deep, caldron-shaped valley, on a river of the same name, 22 m. w.s.w. of Laibach. The descent to the mines is by 787 steps, hewn in the rock, and is easy and free from danger. They are said to be the richest in Europe. Upwards of 330 tons of quicksilver are produced here annually, and about 60 tons of cinnabar (red sulphuret of mercury). Pop. '69, 3,960,

about 400 of whom are regularly employed as miners, the others chiefly in the manufacture of linen and silk fabrics and bone-lace; and in distilling spirits.

IDUME'A. See EDOM.

IDUN, or IDUNA, the name of a goddess of the northern mythology. She was the daughter of the dwarf Svald; but being received among the Æsir, she became the wife of Bragi. Idun possessed a precious apple, by the use of which the gods preserved their perpetual youth. She was carried off by the giant Thiassi, with the assistance of Loki; but the gods sent the latter after her, to bring her back, which he did, after changing himself into a falcon, and Idun into a nut.

I'DYL (Gr. *eidullion*, Lat. *idyllium*, a little image), a term generally used to designate a species of poem representing the simple scenes of pastoral life. It is, however, an error to suppose that the idyl is exclusively pastoral; certainly, there is no warrant for such a notion in the usage either of the ancients or the moderns. Of the thirty *eidyllia* of Theocritus, not more than one-half are pastoral in their character. After the use made of the word by Tennyson, in his *Idyls of the King*, which are epic in their style and treatment, and romantic and tragic in their incidents, it becomes very difficult to say what is not an idyl.

IESI. See JESI, *ante.*

IFFLAND, AUGUST WILHELM, 1759–1814; b. in Hanover, Germany. At the age of 18 he appeared upon the stage at Gotha; in 1779 he acted in Mannheim; in 1796 was made the director of the National theater at Berlin; and in 1811 appointed general director of the royal plays. He wrote many dramas, which were very popular at the time, and several volumes of them have been published.

IF'URIN, the *hades*, or infernal regions of the ancient Gauls, as described in Celtic mythology. A vivid imagination invested the locality with objects of terror, including wild beasts, the mythical dragon, venomous serpents, and an atmosphere impregnated with deadly poisons enveloping the whole. Here the unfortunate, condemned to sustain its tortures, was doomed to eternal misery.

IGASU'RINE, a very poisonous alkaloid, occurring in *nux vomica* with strychnine and brucine. The word is derived from the Malay *igasura* (vomiting nut).

I'GLAU, a very old walled t. of Austria, in the province of Moravia, is situated on the river Iglawa, close to the Bohemian boundary, 49 m. w.n.w. of Brünn. It consists of the town proper and of three suburbs. In the midst of the spacious and beautiful town square stands the guard-house. Iglau carries on spinning, dyeing, and brewing, as well as extensive manufactures of woolen goods and of machinery. Its trade, especially with Poland, is very important. Several very productive silver-works are in operation here. Pop. '69, 20,112.

IGLESIAS, a walled t. of the island of Sardinia, in the province of Cagliari; pop. about 5,000. It is well watered by springs, and corn, wine, and fruits are produced in the surrounding country. In its vicinity are silver and other mines, and the mining operations are prosperous. It has numerous churches, including a cathedral, a fine Episcopal palace, a Jesuits' college, and several convents.

IGLESIAS, JOSÉ MARIA, b. Mexico, 1822. An eminent orator and statesman of the Mexican republic. Before reaching his majority he occupied the chairs of arts and modern languages, respectively, in the colleges of San Gregorio and San Ildefonso, in the city of Mexico. He entered politics as a young man, and speedily attracted attention for his remarkable natural ability. Political preferment rewarded his loyalty to the government, and in 1857 he was a cabinet minister. In 1868 he was a member of the general congress, and the same year was appointed minister of the interior by Juarez, to whose fluctuating fortunes he had clung with unswerving fidelity. In 1873 he became president of the supreme court of justice.

IGLOO'LIK, an island of some historical interest, lies near the e. end of the strait of the Fury and Hecla, in lat. 69° 21′ n., and long. 81° 53′ west. It was named after an intelligent Esquimaux woman, Parry's guide and pilot on his second voyage; and here that navigator passed the winter of 1822–23 from Oct. 30 to Aug. 12. During this time the temperature ranged between—45° and 59° of F., thus yielding a mean of 7° above zero.

IGNA'TIUS, SAINT, bishop of Antioch after 69 A.D., is said to have been a disciple of St. John, and is reckoned one of the apostolical fathers. He bore the surname of *Theophoros*—i.e., one who carries God [or, as Ignatius explained it, "Christ"] in his heart; or, again, as some (Jerome amongst them) wrongly supposed, "one who was carried by God"—i.e., Christ (cf. Mark, ix. 36)—whom, however, according to St. Chrysostom, Ignatius never saw. This legend that he was the little child whom Jesus set in the midst of his disciples, may, however, like the other tradition of his relationship to St. John, be taken as symbolic of his winning, affectionate nature. Ignatius was a true shepherd of his people, one of those meek, earnest, loving spirits to whose beautiful unobtrusive piety Christianity owed its first and best triumphs. Domitian's persecution of the church of Antioch proved him to be no less courageous than pious, and when that storm had passed over, the second and fiercer persecution of Trajan gratified Igna-

tius's wish of being sacrificed for his flock. The story of his interview with Trajan has come down to us. That strong ruler, full of worldly sagacity, just and virtuous after his fashion, could not understand a man so utterly unworldly as Ignatius. He contemptuously called him a *kakodaimon*, or, as we should say, "a poor devil," and in the end condemned him "to be led as a prisoner to Rome, there to be made the food of wild beasts for the amusement [*ad delectationem*] of the people." The sentence was executed 107 A.D., or, according to others, 116 A.D. In the church of Rome his martyrdom is commemorated on Feb. 1; in the Greek church on Dec. 20.

The genuineness of the writings (a liturgy and a little work entitled *Didaché*, quoted by Chrysostom) and epistles ascribed to him—of which 15 (12 in Greek and 3 in Latin) are now extant—and some of which are quoted in the 2d, 3d, and 4th c., and were widely read in the ancient church, has been eagerly discussed and much disputed since the 16th century. The common opinion of scholars (until perhaps the last 20 years) was in favor of the genuineness of seven of the Greek epistles, which are extant in two redactions of different length, and in two corresponding ancient Latin translations—those to the Ephesians, Magnesians, Philadelphians, Trallians, Smyrneans, Romans, and to Polycarp, his contemporary; but even these were regarded as spurious by Daillé, Semler, Hermann, Ernesti, and others, with whom in the main Neander concurs. The controversy received a new impetus by the publication of Bunsen's *Ignatius und seine Zeit* (Hamb. 1847), in which that writer endeavored to establish the genuineness of three of the seven epistles, and the spuriousness of the others; his conclusions were, however, assailed by the great leader of the Tübingen school, F. C. Baur, in his *Die Ignatianischen Briefe und ihr neuester Kritiker* (Tüb. 1848). The most probable view of the seven epistles is that which conceives them to have a basis of genuineness, but to have suffered extensive interpolation. The reason why these epistles have excited so keen an interest, especially among ecclesiastics, is, that the question of church government is believed to hang very much upon them; they are, in fact, a battle-ground between Episcopalians and Presbyterians; and as they seem to favor the hierarchical system of the former, Episcopalians have, as a rule, been strenuous in defense of their Ignatian origin, while Presbyterians have as warmly attacked it. The discovery, in an Egyptian convent, of a Syriac version of three of the epistles—those to the Romans, the Ephesians, and to Polycarp (published by the rev. W. Cureton, formerly of the British museum, under the title of *The Ancient Syriac Version of the Epistles of St. Ignatius*, etc., Lond. 1845), has, on account of its possessing higher claims to be considered genuine than any Greek MSS., led to the conclusion that the common Greek text has been very seriously tampered with—the interpolations consisting often of passages enforcing episcopal authority, and asserting the deity of Jesus Christ.

The text of the writings ascribed to Ignatius is to be found in the various editions of the apostolic fathers, from that of Cotelerius (2d ed. 1724) to the recent and admirable one edited by Gebhardt, Harnack, and Zahn (1876). There are English translations by archbishop Wake and in the *Ante-Nicene Library* (Clark, Edin.). See Zahn, *Ignatius von Antiochien* (1873).

IGNATIUS LOYOLA. See LOYOLA.

IGNATIUS'S (ST.) BEANS, the seeds of the *Ignatia amara*, formerly *strychnos Ignatii*, a tree of the natural order *loganiaceæ*, and nearly allied to that which produces *nux vomica* (q.v.), a native of Cochin-China and of the Philippine islands. The fruit is of the size of a large pear, and contains about 20 brownish seeds, of about the size of olives, rounded on one side, and somewhat angular on the other. These seeds came into the Dutch shops under their present name about the end of the 17th c., but there is some reason to think that they are the *nux vomica* of earlier writers. They contain *strychnia*, and their medicinal uses are similar to those of *nux vomica*.

IGNEOUS ROCKS are those which have been produced from materials fused by heat. They differ from the sedimentary rocks in their origin, structure, and position. They invariably come from below upwards, breaking through the older rocks. The materials of sedimentary strata are fragments of pre-existing rocks, worn, by the action of water, either into a fine mud or into rounded particles, of greater or less size; whereas igneous rocks exhibit either a vitreous structure, as when they have been quickly cooled; or a granular structure, composed of more or less minute crystals, according to the rate of cooling or a vesicular structure, when they have been expanded by the contained gases, or by being brought into contact with water. Some rocks are erroneously called igneous, whose materials, though originally obtained from volcanoes or other subterranean source, have yet been ultimately arranged by water, like the materials of Grahame's island (q.v.). When this fact receives due consideration, many igneous rocks, whose position is now a puzzle, will be better understood. Some of the rocks composing Arthur's seat, near Edinburgh, are undoubtedly of this character, and before a right theory of the hill can be constructed, these must be separated from the truly igneous rocks. In position, also, the igneous may be distinguished from the sedimentary rocks, for they seldom occur regularly stratified, with a parallel upper and under surface, but are generally local, thinning out into wedge-shaped beds, or having that irregular stratification which may be seen in modern lava. They also occur as upright walls or dikes, filling up cracks in the sedimentary strata

The most satisfactory classification of the igneous rocks is based upon their age. The three divisions thus established are each characterized by peculiar mineral and structural differences. The oldest or granitic series (see GRANITE) are generally associated with the paleozoic strata, but are sparingly found in the secondary, and even in the tertiary formations. The special peculiarity of the granitic rocks is the great abundance of silica contained in them; it forms not only a considerable amount of the constituents of the hornblende and feldspar, but crystallizes free in the rock-mass as rock crystal. The trappean rocks (q.v.) are associated with the paleozoic and secondary strata, and are composed of crystals of feldspar and hornblende, varying in their character according to the predominance of the one or other of these ingredients. The volcanic (q.v.) are the newest igneous rocks; they belong to the present period, or the tertiary strata. The chemical ingredients are the same as those that constitute the trappean rocks, but they are somewhat differently built up, augite being the peculiar form the silicate of magnesia and lime assumes in the newer rocks, while it appears as hornblende in the older or trappean series.

IG'NIS FAT'UUS (Lat. "vain or foolish fire") is a luminous appearance frequently seen in marshy places, churchyards, and over stagnant pools, which has puzzled philosophers from the time of Aristotle. It generally appears a little after sunset, as a pale bluish-colored flame, varying in size and shape; sometimes it shines steadily till morning, at other times disappears, and reappears within about half-hourly intervals. It floats in air at about 2 ft. from the ground, is sometimes fixed, and sometimes travels with great rapidity. In general, it recedes on being approached, and *vice versa*, though several successful attempts have been made to light a piece of paper by it. Many efforts have been made to discover its cause; but so varied are its appearances, and so void of any common principle, that these attempts have totally failed. Of the various theories advanced we need mention only two. The first is that the ignis fatuus is due to *phosphureted hydrogen gas* (PH_3), which possesses the power of spontaneous ignition on coming in contact with dry atmospheric air; the gas would be generated by the decomposition of animal matter present in a marshy soil. The motion of the ignis fatuus is accounted for by the flame being communicated along the line of a stream of the gas. The second is that it is due to the combustion of *light carbureted hydrogen gas* (C_2H_4), arising from the decomposition of vegetable matter; but though this supposition satisfactorily accounts for many appearances connected with the ignis fatuus, the gas itself is not spontaneously combustible, and an additional supposition requires to be made to account for its ignition. The probable conclusion is that a number of phenomena similar to the eye, but arising from different causes, are aggregated under the term ignis fatuus. *The ignis fatuus, however, has never been produced artificially.* Electricity and phosphorescence can produce the luminous appearance, but, as far as our present knowledge enables us to judge, they are unable further to imitate it.

It is not a common phenomenon, many distinguished naturalists never having seen it; but it is not unfrequently seen in the n. of Germany, the swampy and moorland districts in the s. and n.w. of England, and in the lowlands of Scotland. It is seen in the above places from the middle of autumn till the beginning of November. In former times, the ignis fatuus, under the names of *Will-o'-the-wisp, Jack-a-lantern, Spunkie*, etc., was an object of superstition among the inhabitants of the districts where it appears, and was believed to be due to the agency of evil spirits attempting to lure the traveler to his destruction; and, unfortunately, there are too many instances on record of travelers mistaking the ignis fatuus for a lamp, and being thus decoyed into marshy places, where they perished.

IGNORA'MUS (Lat. we do not know), the word formerly written by a grand jury on the back of an indictment, meaning that they rejected it. The words now used are "not a true bill," or "not found."

IGNORANCE OF THE LAW, or IGNORANTIA JURIS, is held in law to be no excuse for any breach of contract or duty, nor for crime or other offense. It is absolutely necessary to start with this maxim, otherwise it would be quite impossible to administer the law, for if once a contrary maxim were allowed, it would not only be a premium to ignorance, but would lead to endless and abortive inquiries into the interior of a man's mind. Ignorance of a fact, however, is a different thing. Another kindred maxim of the law is that every man intends the consequences of his own act. Thus, if he shoot at or give poison to a person, it is presumed that he intended to kill such person. So, if he leave a trap-door open in a street or thoroughfare, it is held that he intended people to fall into it and be injured. There is, however, a doctrine called *bona fides*, which, in the case of petty offenses punishable by justices, often tempers the strict and rigid application of the maxim *ignorantia juris neminem excusat;* and even in crimes a judge always takes into consideration, when passing judgment, whether the prisoner or defendant was an ignorant or intelligent person.

IGNORAN'TINES (Fr. *Frères Ignorantins*), a religious congregation of men in the Roman Catholic church, associated for the gratuitous instruction of poor children in sacred as well as secular learning. It was founded in France in the early part of the 18th c. (1724) by the abbé de la Salle, and has gradually been introduced into every Catholic country of Europe. In France this congregation shared at the revolution the

fate of all the other religious bodies; but the brethren, under the name of Brothers of the Christian Schools, were recalled, and re-established under Napoleon in 1806. They are now exceedingly numerous in France, Italy, and Germany, and many branches exist in England and Ireland. In the latter country they possess, especially in Dublin, Cork, Limerick, and Waterford, large educational establishments; and they have published for the use of their schools a series of school-books which are designed to combine with secular knowledge information on the subject of religion, specially designed for Roman Catholic pupils.

IGUALA'DA, a t. of Spain, in the modern province of Barcelona, and situated about 40 m. w.n.w. of the city of that name, on a rising ground on the left bank of the river Noya. It is for the most part closely built, dark, and dirty; carries on manufactures of cotton and woolen goods, hats, and firearms, is the seat of considerable trade, and contains a pop. of 10,000.

IGUA'NA, a genus of saurian reptiles, the type of the family *iguanidæ*, a family which contains many genera and species, and to which belong some of the largest saurians now existing, except those of the crocodile family. Far larger saurians allied to them existed in former geological periods. See IGUANODON. The *iguanidæ* have a lizard-like form and a long tail. The tongue is thick, fleshy, not extensile, and is notched at the tip. They have rows of small teeth on the palate, and their jaw-teeth are remarkable both for their form and mode of insertion, not being lodged in distinct sockets, but fixed in a kind of furrow along the internal face of the jaw-bone, adhering by one side of the bony surface of the root. The food of the *iguanidæ* consists chiefly of leaves and fruits. They are all natives of warm climates. In the genus iguana the back exhibits a row of elevated, compressed, pointed scales along its whole length and which is continued to the extremity of the tail; whilst under the throat is a great dewlap-like pouch. The feet have long toes, not webbed, with sharp claws, well adapted for climbing trees, while the compressed tail is the organ of progression used in swimming. The COMMON IGUANA, or GUANA, is abundant in the West Indies and tropical parts of America, living mostly among trees. It attains a length of 4 or 5 feet. It is of a greenish yellow color, mottled with green, the tail ringed with brown. It is esteemed a most delicate article of food, and is used by all classes of persons. It is often caught by means of a noose thrown over its head; dogs have also been trained to hunt it on some of the West India *keys*, where it has not opportunity of taking refuge in trees. The eggs—which are about the size of those of a pigeon, but have no hard shell, and are laid in the sand—are also eaten, and are very pleasant. Other species of iguana and nearly allied genera are eaten in tropical America, as the horned iguana (*I. cornuta* or *metapoceros cornutus*) of Hayti. The true iguanas are all American.

IGUAN'ODON (iguana, and Gr. *odous*, tooth), a genus of remarkable gigantic dinosaurian reptiles, more abundant in the Wealden beds of Kent, Sussex, and the isle of Wight than any other genus of associated saurians. Their singular structure, differing in many important particulars from any known reptile, long caused great diversity of opinion as to their true position. Dr. Mantell, their original discoverer and their learned expounder, first knew of their existence from some enormous bones, which, notwithstanding their colossal size, he considered reptilian. A large tooth next turned up, whose smooth-worn crown attested its having belonged to a herbivorous animal. Numerous other specimens of teeth were in progress of time discovered, and Dr. Mantell found that they corresponded in a remarkable manner with the teeth of the small American lizard, the iguana, although they exhibited very striking and important differences. Since the original discovery of the teeth, several other portions of this remarkable reptile have been found. The fragmentary and imperfect materials which have yet turned up make any estimate of the size of this animal purely hypothetical. Dr. Mantell's estimate is as much as 70 ft. in extreme length, while prof. Owen considers it to have been not over 28 feet.

The structure of the skeleton is very remarkable. The fragments of the upper and lower jaw show that the head was produced into a short snout, which supported a nasal horn. The vertebral column was somewhat fish-like, the joints being slightly concave on both surfaces; yet it had lofty neural arches, and the sacrum was composed of five anchylosed joints, a structure found in no other reptile. The limbs were long and strong, raising the body some distance from the ground. The largest femur yet found measures 4 ft. 8 in. in length, and the shaft has a circumference of 25 inches. The leg terminated in a three-toed foot, which produced the enormous tridactyle impressions on the argillaceous Wealden beds that were for some time considered to be the foot-prints of huge birds. The discovery by prof. Owen of all the bones of a perfect foot, however, conclusively connects these impressions with the iguanodon. His figure, in a recent volume of the paleontographical society's publications, exhibits a foot 21 in. long by 9½ in. broad.

The teeth of the iguanodon, while bearing a general resemblance to those of the iguana, were much more complicated both in external form and internal structure than in any other known reptile. In all other known reptiles the vertically flat teeth are always sharp-edged, and fitted only to cut off the plants on which they feed, but the worn

crowns in this animal show that the iguanodon thoroughly triturated its food before swallowing it.

IH'LANG-IH'LANG, a strong and rich perfume from a fine forest-tree of the Philippine and Malay islands, the *unona odoratissima*. The perfume is distilled from a volatile oil yielded by the flowers, and is valued at about $250 a pound.

IHRE, JOHAN, an eminent Swedish scholar of Scottish extraction, was b. at Lund in 1707, and educated at the university of Upsala, where he acquired a great reputation, and carried off the highest honors. He subsequently traveled in France and England, was appointed under-librarian to the academy of sciences on his return to Sweden, and rose through a variety of offices to be professor of belles-lettres and political economy (1748). He died in 1780. Ihre's principal work is his *Glossarium Suiogothicum* (1769), a work of great talent and erudition, which may be regarded as the foundation of Swedish philology. It was got up at the cost of the state, which gave Ihre $10,000 to execute it. His numerous academical disputations, amounting to upwards of 450, are still valuable, especially those on the Mœso-Gothic version of the gospels by Ulfilas.

IKUPA, the principal river of Madacasgar (q.v.).

IL'CHESTER, a small and decayed t. of England, in the co. of Somerset, is situated in the rich valley of the Yeo or Ivel—from which it derives its name—33 m. s.s.w. of Bath. The principal buildings are the parish church, an ancient structure surmounted by a low octagonal tower, and the county jail. Ilchester, supposed to be the Ischalis of Ptolemy, was the principal station of the Romans in this region, and was fortified by them with a strong wall and ditch, both still traceable. Numerous Roman remains have been found here. Ilchester is the birthplace of Roger Bacon. Pop. '71, 743.

ILE-DE-FRANCE, one of the old provinces of France, having Paris as its capital, and now mostly comprised in the departments of Seine, Seine-et-Oise, and Oise. During the last century of the Carlovingian dynasty, the Ile-de-France was possessed by a race of powerful nobles, who latterly took the title of dukes of France. One of the most able of these was Hugo or Hugues, surnamed Le Blanc, or Le Grand, who, for 20 years previous to his death (956), virtually wielded the sovereign power under the Carlovingian kings Louis IV. and Lothaire. His son, Hugo Capet, eventually became the actual sovereign. See CAPETIAN DYNASTY.

I'LETZK, or ILETZKAÏA ZASHCHITA, a small t. and fort in eastern Russia, on the border of the Kirghiz territory (government of Orenburg), situated on the river Ilek, near its confluence with the Ural, in lat. 51° 9' n., long. 54° 59' east. The town was founded by Cossack emigrants in 1737, and contained in 1867 a population of 2,493 inhabitants. It is remarkable for its quarries of rock-salt, the richest in Russia. The salt-beds of Iletzk were formerly worked by the native Bashkirs, but since 1754 both the extraction and sale of the salt are monopolized by the government, and are the source of considerable revenue. All the country round Iletzk, especially along the river Solianka, is one continual layer of salt, covered with a sandy or clayey alluvion, 3½ to 4½ ft. thick. The thickness of the salt-bed is not yet thoroughly ascertained, notwithstanding many investigations, from Pallas up to the present time. The Iletzk salt is considered the best in Russia. On the surface of the bed, cubic blocks of salt are found, pure and transparent like crystal, and weighing from 3 to 30 lbs. each. Various small articles are manufactured out of such blocks, and the common people ascribe to them a healing virtue in ophthalmic disease. Near Iletzk there are two lakes, one of which is salt and warm, the other acid.

ILEUM. See DIGESTION, ORGANS OF.

ILEUM (*ante*), the lower and longer portion of the small intestine, so called because of its numerous convolutions and twists and windings (Gr. εἰλεῖν, to twist). It terminates below in the cæcum, the lower sac-like portion of the large intestine called the colon. The other and upper portion of the small intestine lies between the ileum and the stomach, and consists of the duodenum and the jejunum (q.v.), the latter being next above the ileum, while the duodenum is that portion immediately below the stomach, and is larger in diameter than either jejunum or ileum. The duodenum is about 10 in. long, the jejunum about 6 ft., and the ileum about 12 ft., or about two-thirds of the whole of the small intestine, and it principally occupies the hypogastric and right iliac regions of the abdomen. See REGIONS OF THE BODY. It is the principal seat of enteritis, or inflammation of the mucous coat of the small intestine (Flint), and also the principal seat of lesion in typhoid fever (q.v.), in which the glands of Peyer become inflamed and ulcerated.

ILEUS, or ILIAC PASSION, is regarded by some writers as a distinct disease, but is in reality the closing stage of the severest forms of enteritis, or of colic, and is often connected with some irremovable mechanical obstruction. It may indeed occur in any case in which the contents of the bowel cannot find their way onwards. The peristaltic action of the intestine is inverted; there is intense vomiting, and even feculent matter is discharged by the mouth. Desperate as the condition of the patient is, his case is not absolutely hopeless; but as recovery, when it occurs, is due rather to nature than to art, it is unnecessary to enter into the subject of treatment.

I'LEX, a tree often named in the Latin classics, the evergreen oak or holm oak (*quercus ilex*). See OAK. It is a native of most parts of the s. of Europe and of the n. of Africa, often attaining large dimensions, as it sometimes does where planted in Britain. It grows in general singly or in small groups, and loves the vicinity of the sea. Its leaves are ovate-oblong, acute, leathery, hoary beneath; but they vary much in some respects, from the size of a sloe-leaf to that of a beech, and from being very spiny at the edge to perfect evenness. It is a very ornamental tree, and has not been so much planted in Britain as it deserves. Its wood is very hard and heavy, tough, durable, and useful, particularly for axles, pulleys, screws, and whatever is to be subjected to much friction. The acorns are of various quality, sometimes bitter, and sometimes sweet and eatable.—In modern botany, *ilex* is the generic name of the holly (q.v.).

IL'FRACOMBE, a small market t., seaport, and watering-place of England, on the n. coast of the co. of Devon, is finely situated amid picturesque irregular hills, on a cove or inlet of the Bristol channel, 11 m. n.n.w. of Barnstaple. The harbor is formed by ramparts of rock, and furnished with a light-house and a pier 850 ft. in length. The bathing establishment is a Doric building, erected here in 1836, and supplied with sea-water from the shore by means of a tunnel. The town is chiefly dependent upon its wealthier residents and its summer visitors; but an active fishery and coasting-trade are also carried on. Pop. '71, 4,721.

ILHA'VO, a fishing t. of Portugal, in the province of Beira, near the Atlantic. Pop. 8,000.

IL'IAC AR'TERIES. The aorta (q.v.) divides at its lowest point—which is usually on the left side of the body of the fourth lumbar vertebra—into the two common iliac arteries, which pass downwards and outwards on each side to the margin of the pelvis for about 2½ in., and then divide into the external and internal iliac artery of either side. The external iliac passes obliquely downwards and outwards to the femoral arch, when it enters the thigh and becomes the femoral artery. The internal iliac is a short vessel, about an inch and a half in length, which divides into an anterior and a posterior trunk. The anterior trunk divides into several branches, which supply the bladder, the rectum, the generative organs, and muscles both within and on the outside of the pelvis, with arterial blood; while the branches of the posterior trunk mainly supply muscles within and on the outside of the pelvis. The importance of the internal iliac artery in carrying on the circulation in uterine life is noticed in the article FETUS.

ILIJATS'. See ILIYATS.

ILINIZA, or ILINISSA, a volcano of the Cordilleras in Ecuador, South America, 10 m. s. of Quito. There are two peaks, 17,380 ft. high, visible from a great distance at sea.

ILION, a village of Herkimer co., N. Y., in the town of German Flats, on the s. bank of the Mohawk river, and on the Erie canal; pop. '70, 2,876. Horse railroads connect it with Mohawk and Herkimer. It was incorporated 1865. It has two weekly newspapers, and large factories for fire-arms, sewing-machines, and agricultural implements.

ILIS'SUS. See ATHENS and ATTICA.

IL'IUM. See PELVIS.

ILIUM (*ante*), a portion of one of the bones of the pelvis, the os innominatum. In the undeveloped child it is a distinct portion, which afterwards becomes united to the pubis in front and to the ischium behind and below. It is the hip-bone or haunch-bone. The word has the same derivation as ileum (q.v.). Some suppose that the root *εἰλεῖν* refers to the curving or winding of the crest of the ilium, and that the latter does not get its name because it partly supports the intestine ileum.

ILIUM. See TROY.

ILIYATS, or ELIAUTS, a nomadic tribe of Persia and Turkistan, mostly of Turkish, Arabic, or Kurdish descent. They are Mohammedans of the Sunni sect. They have no settled abode, but live in tents, moving from place to place, according to climate or season. They have large flocks and herds, and some tribes live by plunder. Each tribe pays tribute in cattle for the use of grazing ground, money not being known among them.

IL'KESTON, a thriving market t. of England, in the co. of Derby, and situated 10 m. n.e. of the town of that name, on an eminence in the valley of the Erewash. Manufactures of hosiery and lace are here carried on, and a number of the inhabitants are employed in the coal and iron works of the vicinity. Pop. '71, 9,662.

ILLE-ET-VILAINE, a maritime department in the n.w. of France, formed out of a portion of the old province of Bretagne, is quadrangular in shape, and lies between the English channel and the department of Loire-Inférieure. Area, 2,590 sq.m., or 1,646,670 sq. acres, of which 1,016,580 acres are arable land; pop. '76, 602,712. It is watered chiefly by the rivers from which it derives its name—the Vilaine, and its tributary, the Ille. The usual grain crops are raised in sufficient quantity to meet the wants of the

population. Flax and hemp are extensively produced, and the cider of this district is esteemed the best produced in the country. Cattle are reared in great numbers, iron mines are worked, and great varieties of linen and woolen fabrics are manufactured. The department is divided into six arrondissements—Rennes, Fougères, Montfort, St. Malo, Vitré, and Redon. Rennes is the capital, and St. Malo the principal seaport.

ILLEGITIMACY. See LEGITIMACY; BASTARDS.

ILLIC'IUM, a genus of trees of the natural order *magnoliaceæ*, having flowers with three or six petal-like sepals, numerous petals arranged in several rows, and numerous stamens and pistils; the capsules arranged in a star-like form, opening upwards, and each containing a single seed. The species are few, but very widely distributed. The most important is *I. anisatum*, the fruit of which is known as star anise, or Chinese anise. See ANISE. This tree is held in high estimation among the Japanese, and is planted near their temples, as their gods are supposed to delight in it.—Among the other species is *I. floridanum*, a shrub with fine pendant clusters of dark purple flowers, native of Florida and Louisiana, of which the leaves are very fragrant, the capsules also smelling of anise, though more faintly than those of the Chinese tree. Similar in fragrance is *I. parviflorum*, another Floridian species.

ILLIMA'NI, one of the principal mountains of the Bolivian Andes. See ANDES.

ILLINOIS', a river of North America, is formed in the n.e. portion of the state of Illinois by the union of the Kankakee and Des Plaines, flows s.w., and joins the Mississippi 20 m. above the mouth of the Missouri. It is 500 m. long, and is navigable for 245 miles. It is broad, deep, and sluggish, and widens occasionally into lake-like expanses. It is connected by a canal with lake Michigan.

ILLINOIS, one of the United States of America, extending from 36° 56′ to 42° 30′ n. lat., and 87° 35′ to 91° 40′ w. long., being 388 m. long, and 212 wide; containing an area of 55,405 sq.m., or 35,459,200 acres. It is bounded n. by Wisconsin; e. by lake Michigan, and the state of Indiana, from which it is partly separated by the Wabash river; s. by the converging rivers Mississippi and Ohio, which separate it from Missouri and Kentucky; and w. by the Mississippi, which separates it from Missouri and Iowa. The state is divided into 102 counties; the capital is Springfield, near the center of the state, and the most important towns are Chicago, the principal port on lake Michigan, Galena and Alton on the Mississippi, and Cairo, at the southern terminus of the Central railway, and the confluence of the Ohio and Mississippi rivers. The population of the state has increased with marvelous rapidity. In 1810 it was 12,282; in 1820, 55,211; in 1830, 157,445; in 1840, 476,183; in 1850, 851,470; in 1860, 1,711,753; and in 1870, 2,511,096. More than half the people of Illinois were born in other states or foreign countries, a large number being Irish and Germans. In 1850 there were but 707 paupers in a population of 851,470. The state of Illinois is generally level, having few hills and no mountains. The lowest portion is but 340 ft., and the highest only 1,150 ft., above the gulf of Mexico. It is nearly covered by fertile prairies; while river bottoms, with a soil of vegetable mold 40 ft. in depth, have produced heavy crops of maize for many successive years without manuring. The country is so level that the canal which unites lake Michigan with Illinois river and the Mississippi is fed by water pumped from the lake to a height of 12 feet. The principal rivers, besides those which form the boundaries, are the Illinois and Rock rivers, and their tributaries. The whole state is of limestone formation, with rich lead deposits in the n.w., and a large portion of the great bituminous coal formation, 375 m. long and 200 wide, lying in this and the adjoining states. The climate is mild, with an average of 77° Fahr. in summer, and 33½° in winter, but ranging from 20° below to 100° above zero; it is also healthy, except in swamplands or river-bottoms, which are subject to fever and ague and bilious diseases. The productions are wheat, maize, tobacco, cattle, hogs, apples, pears, peaches, grapes, etc. There were in 1865, 3,157 m. of railway in operation: in 1875 the mileage had increased to 6,742 miles.

In 1870 Illinois contained 11,050 public schools, 6 universities, and 779 other schools. In the same year it produced 30,128,405 bush. of wheat, 129,921,395 bush. of Indian corn, and 42,780,851 bush. of oats. In 1830 the Mormons built the city of Nauvoo, on the Mississippi; but in 1844 their prophet, Joseph Smith, was killed by a mob; and his followers, 20,000 in number, made their exodus across the plains to the territory of Utah.—Illinois was first explored by La Salle, and the French missionaries and Indian traders, who formed the earliest settlement at Kaskaskia, in 1673. Ceded by France to Great Britain, and then to the United States, it remained a portion of the North-west territory, until its organization as a state, with a governor and legislature, in 1818.

ILLINOIS (*ante*), is the eighth state admitted to the union under the federal constitution, and by the census of 1870 the fourth in population; of 1880, the same. It lies between lat. 36° 59′ and 42° 30′ n., and long. 87° 35′ and 91° 40′ w.; extreme length n. and s., 385 m.; extreme breadth e. and w., 218 m.; area, 55,410 sq.m., or 35,462,400 acres. Its name is derived from its principal river, and is of mixed Indian and French derivation. The first white settlements in the state were made by the French from Canada, who followed the explorations of Marquette and La Salle. The latter, having crossed the lakes in 1679, descended the river which he named Illinois and built a fort at the

foot of lake Peoria, a broad expansion of the stream for a distance of some 25 m. about midway in its course through the state. After descending the Mississippi for some distance he returned to Canada, but came again in 1682 with a colony, and founded Kaskaskia, Kahokia, and some other towns. These settlements, early in the 18th c., were visited by Jesuit missionaries, who described the country as a new paradise. The colonists were on the most friendly terms with the Indians, and finally degenerated to their level. In 1762 Canada and the whole American territory e. of the Mississippi passed under British control, but the Illinois settlements were not disturbed. After the peace of 1783 the Illinois country was ceded to the United States, and in 1787 the whole national domain n. of the Ohio was organized under the name of the North-west territory, by an ordinance which protected it forever from the inroads of slavery. In 1800 this immense territory contained only a little more than 50,000 inhabitants. In the same year Ohio was organized as a separate territory; in 1805 Michigan was set apart in the same way; and in 1809 the territory of Indiana was organized. What remained of the original North-west territory was soon organized under the name of Illinois. It embraced, besides the state itself as at present bounded, Wisconsin and part of Minnesota, and contained a white population of a little over 12,000. The Indians at this time were very troublesome, and the settlement of the territory was consequently much impeded. After the close of the war of 1812 Indian hostilities ceased, and the territory began to be occupied by emigrants from the eastern states. In 1818 Illinois, with its present boundaries, was admitted to the federal union as a state. The census of 1820 reported the population to be 55,211; that of 1830 showed it to be 157,445. In 1831 there was further trouble with the Indians, which culminated in the Black Hawk war and the removal of all the Indian tribes from the state. After this the population increased rapidly, congress made an appropriation for the improvement of the harbor of Chicago, and the construction of the Illinois and Michigan canal was begun. In spite of the financial revulsion of 1837, the effects of which upon the new state were of the most serious character, the census of 1840 showed a population of 476,183, a gain of 318,738 in ten years. In 1840 the Mormons settled at Nauvoo, intending to make it their "Jerusalem." Their doctrines and practices were very distasteful to their neighbors, and a great excitement was the result. Joseph Smith, the founder of the sect, and his brother Hyram, were arrested and put into jail at Carthage for destroying a press established by a party of Mormons to oppose polygamy. They refused to submit to an arrest by the civil officer, and the sect, numbering 20,000 people, organized for their protection. They finally surrendered to the military, but the public mind had now become so inflamed that before they could be tried, the jail was invaded by a mob and they were killed. The sect soon afterwards removed to Utah. The population of the state in 1850 had increased to 851,470. The grant by congress of extensive sections of the public lands to aid in the construction of the Central railroad, which was completed in 1856, had the effect of drawing multitudes of people to the region through which it passed, and of building up many flourishing towns and villages, and in the course of a few years every acre of government land in the state was sold. Kaskaskia was the territorial capital; the state capital from 1818 to 1836 was at Vandalia. At the last mentioned date it was removed to Springfield, where it has since remained.

The streams of Illinois, with the exception of a few short ones in the n.w. part of the state, which empty into lake Michigan, find their way directly, or indirectly, to the Mississippi. The largest river wholly within the state is the Illinois, which is formed by a junction of the Des Plaines from Wisconsin and the Kankakee from Indiana, and flows nearly 500 m. before reaching the Mississippi. It is navigable for 245 m. from its mouth. The Chicago river, which formerly emptied into lake Michigan, now flows out of that lake by an artificially defined channel into the northern branch of the Illinois. The chief affluents of the Illinois are the Fox, Spoon, and La Main rivers, and Crooked creek from the n. and w., and the Vermilion, Mackinaw, and Sangamon rivers, and Macoupin creek from the s. and east. The Kaskaskia rises in Champaign co. and runs parallel to the Illinois for 250 m., flowing into the Mississippi near the s. border of Randolph county. Rock river, which rises in Wisconsin, flows through the n.w. portion of the state, and enters the Mississippi at Rock Island. The Wabash, which divides the state from Indiana on the e. for a considerable distance, receives the waters of the Big Vermilion, Embarras, and Little Wabash, and flows into the Ohio in Gallatin county. The Big Muddy, an affluent of the Mississippi between the Ohio and the Kaskaskia, drains a considerable extent of territory. The surface of the state is a gently inclined plane descending from the n.e. in a s.w. direction toward the Mississippi. With the exception of a low ridge extending across the southern end of the state, there is not a single elevation that can be properly called a mountain. In the north-western corner, where there are extensive deposits of lead, the surface is broken into small hills, and there are bluffs on the Mississippi and Illinois rivers, which, in contrast with the prairies, present a picturesque appearance. The largest portion of the state consists of level or gently undulating prairies, with a rich and deep soil. Geologists think that anciently the waters of the great lakes flowed into the gulf of Mexico through the channels of the Illinois and the Mississippi. It is also conjectured, from the diluvial character of the soil, that the larger portion of the surface of the state was once the bed of an immense lake. The loam and mold which form the surface are underlaid by an almost solid bed of clay

which prevents the moisture from wasting. In the river bottoms the mold is sometimes more than 25 ft. deep, and of inexhaustible fertility. In almost every part of the state the plow is never obstructed even by a pebble. Over these extensive prairies, in their wild condition, once roamed innumerable herds of buffaloes, which fattened upon their rich vegetation. The prairies are generally interspersed with islands of oak and other forest trees, and there are occasional wooded belts where the limestones and sandstones above the coal formations come to the surface.

The state has an immense field of bituminous coal, 375 m. in length and 200 m. in breadth, which furnishes a supply of fuel sufficient not only for home use, but for extensive exportation, so that the demand for wood is limited. But for this abundance of coal the state must ere now have been utterly denuded of her forests. The trees most abundant are oak, black walnut, sugar maple, ash, locust, elm, hickory, linden, persimmon, pecan, cottonwood, sycamore, buckeye, tulip, poplar, beech, and black birch. Yellow pine, cypress, and cedar are found near the Ohio river. The iron ores are of an inferior quality, but are sometimes utilized by mixing them with those brought from Missouri and lake Superior. Lead, with a mixture of silver, is found in Joe Daviess co., in the n.w. corner of the state, and is mined extensively. Veins of copper ore are found in the n. part of the state, and worked with profit. Zinc also is found in the same quarter. Limestone of good quality for building and burning, and freestone, marble, and gypsum, are found in some places. Salt springs exist in Jackson, Vermilion, and Gallatin counties, and sulphur and chalybeate springs in Jefferson county. In Hardin co., on the Ohio river, is a cave 80 ft. sq. and 25 ft. high, which in the early days of this century was the resort of criminals and outlaws.

Many of the wild animals have been exterminated. Few deer are left, and bears, panthers, and wildcats are rare. The prairie wolf is sometimes met with in sparsely settled regions, and foxes, hares, and squirrels are numerous. Game-birds, such as the wild turkey, prairie-hen, and grouse, are plentiful. Fish of good quality and in considerable variety are found in the rivers and lakes. The insect tribes are numerous, and a few of them are injurious to vegetation. The climate of the state varies with the degrees of latitude. In the n. the summer heat is intense, the winter cold severe. There being no mountains to break the force of the winds they are very cutting in the cold season, while the summer heat is mitigated by them. The atmosphere is rarely in a calm condition. In the extreme n. part of the state the mean annual temperature is 47½°, while in the extreme s. it is 58½°, and in the center 54°. The climate, except in the low swampy bottom lands, where bilious and intermittent fevers prevail, is exceedingly favorable to health. The proportion of clear to cloudy or rainy days is a little more than two to one.

As an agricultural state Illinois stands in the first rank. It contained in 1870 10,329,952 acres of improved and 6,552,909 of unimproved land; and, of the unimproved lands, 1,491,331 acres were wooded. Total number of farms at the same date, 202,803; of which 303 contained 1000 acres or over; 1367 from 500 to 1000 acres; 65,940 from 100 to 500 acres; 68,130 from 50 to 100 acres; and 53,240 from 20 to 50 acres. The estimated total value of these farms was $920,506,346; of agricultural implements, $34,576,546; of farm products, $210,860,585; of orchard products, $3,571,789; of market gardens, $765,992; of animals sold for slaughter, $56,718,944; of home manufactures, $1,408,015; of forest products, $1,087,144; total, $1,379,252,100—an immense result for a state which, 70 years before, had only a little more than 12,000 inhabitants. In 1873 the value of the cultivated lands was estimated at $1,600,000,000; the actual property of the state, real and personal, at $2,800,000,000. The chief productions are wheat, corn, rye, oats, barley, flax, buckwheat, potatoes, sweet potatoes, tobacco, peas, beans, wool, cheese, hops, maple sugar, honey, and every variety of garden vegetables. The state in 1870 exceeded all others in the Union in the product of wheat, corn, and oats. It contained more swine and horses than any other state, and was exceeded by only New York in the aggregate value of its live-stock. The wheat crop of 1879 was estimated at 45,417,661 bush., valued at about $40,000,000. The corn crop of the same year was 54,664,569 bush., valued at $12,059,162.

In manufactures, by the census of 1870, Illinois ranked sixth among the states; in the value of the products of butchery, distilled liquors, planed lumber, and pork packed, she stood before all others. The number of her manufacturing establishments was 12,579; persons employed therein, 82,979, of whom 73,045 were men, 6,717 women, and 3,217 children; capital invested, $94,368,057; wages paid, $31,100,244; annual product, $205,620,672. The number of flouring-mills was 681; capital invested in them, $12,931,600; persons employed, 3,581; wages paid, $1,704,778; value of products, $39,413,618. Next in importance was the business of packing pork and other meats, the capital invested in which was $6,921,000; persons employed, 2,236; wages paid, $448,560; value of products, $19,818,851. In the manufacture of malt and distilled liquors 1955 persons were employed; wages paid, $1,031,142; capital invested, $7,397,900; value of productions, $12,042,976. The value of the lumber produced was $11,382,649; of agricultural implements, $8,880,390; iron wares, $7,738,443; clothing, $8,407,005; carriages and wagons, $6,019,291; machinery of all descriptions, $6,298,794; tobacco in its various forms, $4,319,716; leather, $4,148,163; woolen goods, $3,725,630; printing and publishing, $2,727,549; furniture, $2,982,592; coopering, $2,501,531; boots and shoes, $2,298,-

136; oils, animal and vegetable, $2,642,733; saddlery and harness, $2,581,416; sashes, doors, and blinds, $2,316,320; tin, copper, and sheet-iron wares, $2,194,812; confectionery goods, $1,948,710; bakery products, $1,732,885; bricks, $1,638,764; marble and stone work, $2,098,209; soap and candles, $1,250,930; grease and tallow, $1,412,900; paper, $1,188,400; railroad cars, $1,010,007.

The railroads of Illinois are more numerous and of a greater extent of track than those of any other state in the union. This is owing in part to the favorable situation of the state for commerce and travel, and partly to its almost level surface, which reduces the cost of construction to the lowest point. The total number of miles of railroad track in the state in 1874 was 6,116, occupying a space of nearly 60,000 acres, and valued, with right of way and improvements, at more than $40,000,000. The cost of equipping these roads is estimated at nearly $241,000,000; amount of preferred stock, $17,812,000; amount of common stock, $131,472,000; of bonded debt, $125,000,000; of floating debt, $4,180,000; gross earnings for the year, $43,188,000; operating and general expenses, $29,521,000; excess of earnings over expenses, $13,474,000; freight carried, 10,148,427 tons; number of passengers, 11,464,217. The most important of these roads, with their length in miles, are the following: the Illinois Central and its branches, 705; Chicago and Alton and branches, 548; Chicago, Danville and Vincennes, and branches, 783; Chicago, Rock Island and Pacific, 181; Cairo and Vincennes, 156; Indianapolis, Bloomington, and Western, 131; Indianapolis and St. Louis, 186; Ohio and Mississippi, 147; Rockford, Rock Island, and St. Louis, 318; St. Louis and Southeastern, 180; Springfield and Illinois Southeastern, 221; St. Louis, Vandalia, and Terre Haute, 158; Toledo, Peoria, and Warsaw, 230; Toledo, Wabash, and Western, 386; Western Union, 127. The Illinois Central pays to the state 7 per cent of its gross earnings, amounting to over $50,000 per annum, and is not otherwise taxed. The other roads pay taxes upon their assessed valuation. The companies are required to make written reports under oath, at stated intervals, and to obey the rules as to reasonable maximum rates of fare and of freight prescribed by commissioners appointed by the state.

In 1874 the debt of the state amounted to $1,706,750; indebtedness of some of the counties, cities, and towns, represented by outstanding railroad bonds, in 1870, $13,500,000; other indebtedness of counties, cities, and towns, $37,300,000. The commercial facilities of Illinois are scarcely rivaled by those of any other state. The Mississippi washes its whole w. boundary, while the Wabash and Ohio are navigable on one-half the e. and the whole of the s. boundary; the Michigan and Illinois canal, 100 m. long, connects lake Michigan, through the Chicago and Illinois rivers, with the Mississippi; while numerous railroads open the way for freight and passengers from every part of the state to the northern lakes and the Ohio and Mississippi rivers. The traffic through these channels is immense, and there are no recent statistics that give an approximate idea of its amount. Large quantities of Illinois production go to swell the commerce of St. Louis, Indianapolis, Louisville, and Cincinnati, while vast amounts are shipped directly and without breaking bulk to Boston, New York, Philadelphia, Baltimore, New Orleans, and San Francisco. The foreign commerce of the state, which is rapidly increasing, is chiefly carried on through the port of Chicago. There were in the state in 1874, 152 national banks with a capital of $20,338,670. There were also 12 state and savings banks doing a discount and deposit business, with a capital of $3,300,000, and 217 private banks. The insurance companies were mostly ruined by the Chicago fire of 1871, but new ones are rapidly taking their places. In 1873 eight new companies were in operation, with an aggregate capital of nearly $2,000,000, and assets amounting to $2,568,000. There were besides at the same time 6 life-insurance companies—all in Chicago—having an aggregate capital of $1,800,000, and assets amounting to $3,355,000. In 1879 the number of fire, marine, and inland insurance companies was 171. The state is as well supplied with telegraphs as with railroads, the lines extending in the aggregate more than 10,000 miles.

The census during four decades before 1840 showed the presence of a few slaves, introduced by emigrants from the southern states in defiance of the ordinance of 1787. Efforts were indeed made here, as in Indiana and Ohio, to treat that ordinance as a dead letter, and give slavery a foothold n. of the Ohio river, but they proved abortive. The pop. of Illinois in 1870 was 2,539,891, of which 2,024,693 were natives of the country, 515,198 of foreign birth, and 28,762 were colored; males, 1,316,537; females, 1,233,354. The charitable and correctional institutions of the state are: the penitentiary at Joliet, which has usually from 1200 to 1400 inmates; the reform school at Pontiac, with accommodations for but 150 inmates, too small for the public needs; the institutions for the deaf and dumb and the blind, at Jacksonville; the charitable eye and ear infirmary at Chicago; insane asylums at Jacksonville, Elgin, and Anna; the institution for the feeble-minded at Jacksonville; and the home for children of deceased soldiers at Normal. These institutions are under the supervision of a state board of commissioners, appointed by the governor with the consent of the senate. The public-school system is well organized and efficient. Appropriations of public money for sectarian schools are forbidden in the constitution. Every school district is required to maintain a free school during five months of every year, the tax for which is limited to 2 per cent for educational and 3 per cent for building purposes upon the assessed value of its taxable property. The elements of natural science are required to be a part of the common

school course. Teachers are required to produce a certificate of competency from the county superintendent. The amount of the state school fund in 1872 was $12,764,495. The total income from this fund and from the current school funds was $7,560,122. The income from current funds was derived chiefly from the two-mill tax and the ad-valorem tax in the districts—$900,000 from the former, and $5,292,942 from the latter. The number of school districts in 1872 was 11,231; of public schools, 11,376, of which 88 were high and 611 graded; number of teachers—male, 9,094; females, 11,820; average monthly salaries of teachers—males, $50; females, $39; total approximate value of school property, $19,876,708; number of volumes in district libraries, 54,286; number of private schools, 426, with 34,784 pupils. The number of persons in the state unable to read and write was 6,753. The state normal university at Normal for training teachers comprises, besides the usual departments, a model school. It employs from 12 to 15 instructors, and usually contains from 700 to 800 pupils, a large proportion of them in the model school. There is another normal university at Carbondale, in the s. part of the state, and, besides the two state institutions, there are county normal schools in Cook, Peoria, and Joe Daviess counties. In 1879 a law was enacted to enforce the attendance at school for at least 12 weeks in each year of every child between the ages of 8 and 14. According to the census of 1870 Illinois had 26 universities and colleges, with 223 instructors and 4,657 students; 32 academies, with 201 instructors and 4,590 pupils; 2 law schools, with 3 instructors and 61 students; 2 medical schools, with 19 instructors and 358 pupils; 9 theological schools, with 28 instructors and 555 students; 2 schools of agriculture, 2 of commerce, and 2 of art and music. There were in 1873 9 institutions for the superior instruction of girls, all but one under the patronage of some religious denomination; 2 of these are Roman Catholic, 2 Methodist, 2 Presbyterian, 1 Baptist, and 1 Congregational. The number of medical schools in 1873 was 6, with 89 instructors and 603 students; one of these schools was homeopathic. The theological schools in 1873 were of the following denominations: 2 Presbyterian, 2 Baptist, 1 Methodist, 1 Congregational, 1 Protestant Episcopal, 1 United Presbyterian, 1 Christian, and 1 Lutheran; instructors, 48; students, 260. The number of libraries, private and public, as reported by the census of 1870, was 13,570, containing 3,323,914 volumes. The Chicago fire of 1871 destroyed the largest of these libraries. The number of newspapers and other periodicals in 1870 was 505, circulating 113,140,492 copies annually. Of these publications, 39 were daily, 10 tri-weekly, 4 semi-weekly, 364 weekly, 11 semi-monthly, 72 monthly, 2 bi-monthly, and 3 quarterly. The religious organizations in 1870 numbered 4,298, having 3,459 church edifices, and property valued at $22,664,283. The leading denominations are: Baptist, Christian, Congregational, Episcopal, Friends, Jewish, Lutheran, Methodist, Presbyterian, Roman Catholic, United Brethren in Christ, Unitarian, and Universalist.

The present constitution of Illinois was adopted in 1870. The senate consists of 51 members, elected for 4 years; the house of representatives of 153 members, elected for 2 years. The legislative sessions are biennial. The governor and other executive officers (except the treasurer) are elected for 4 years, and cannot serve for two consecutive terms. The judicial department is composed of a supreme court, circuit courts, county courts, justices of the peace, and police magistrates. The supreme court, including the chief justice, is composed of 7 justices, each of whom is elected by the people of a judicial district for a term of 9 years. The chief justice is chosen by his associates. The circuit judges are elected for 6 years, the county and probate judges for 4 years. Voters must have resided in the state one year, in the county 90 days, and in the election district 30 days next preceding an election. The electoral votes of Illinois for president and vice-president have been cast as follows: 1820, 3 for Monroe and Tompkins; 1824, 2 for Jackson and 1 for Adams for president, and 3 for Calhoun for vice-president; 1828, 3 for Jackson and Calhoun; 1832, 5 for Jackson and Van Buren; 1836, 5 for Van Buren and R. M. Johnson; 1840, 5 for Van Buren and Johnson; 1844, 9 for Polk and Dallas; 1848, 9 for Cass and Butler; 1852, 11 for Pierce and King; 1856, 11 for Buchanan and Breckinridge; 1860, 11 for Lincoln and Hamlin; 1864, 16 for Lincoln and Johnson; 1868, 16 for Grant and Colfax; 1872, 21 for Grant and Wilson; 1876, 21 for Hayes and Wheeler; 1880, 21 for Garfield and Arthur.

ILLINOIS, the name of a community of tribes of Indians, partly belonging to the great Dakotah family, and inhabiting the territory which afterwards became the state of Illinois, and also lands w. of the Mississippi. They included the Kaskaskias, Peorias, Tamaroas, Moingwenas, Cahokias, and Michigameas, principally Algonquins. They were a warlike race, aided the French in their Indian wars, and fought the Sacs and Foxes on their own account. Only a remnant of this family exist, on reservation in the Indian territory.

ILLINOIS COLLEGE, at Jacksonville, Morgan co., Ill., was organized by Congregationalists as a non-sectarian institution in 1830. It has a library of 10,000 volumes. Number of professors in 1878, 9; number of students, 87.

ILLINOIS INDUSTRIAL UNIVERSITY, at Urbana, Champaign co., Ill., was organized in 1868, its chief endowment being derived from the public lands which fell to the share of the state of Illinois under the act of congress of July 2, 1862, and which were to be devoted to the establishment of colleges of agriculture and the mechanic arts. This endowment amounts to $320,000, and the university has 25,000 acres of land

still unsold, valued at from $5 to $10 per acre. Its annual income, derived from endowments, fees, and state appropriations, amounts to about $75,000. Its grounds, including the military campus, the college campus, and the farm, orchards, gardens, nurseries, arboretum, etc., embrace 623 acres. The main college building is one of the largest and best of its kind in the country, being four stories high and 214 ft. long, with a depth on the wings of 122 feet. It contains an auditorium, library, museum, art gallery, physical laboratory, and over thirty lecture-rooms. Besides this there are one large and two small dormitories, a large mechanical and military building, a large chemical laboratory, a green-house, and several farm houses and other farm buildings. The chemical laboratories contain desks and apparatus for 200 students; the physical laboratory has accommodations for 50 students; and there is besides a laboratory for students in mechanical engineering and architecture. There is a large museum of natural history, including zoological, geological, and mineralogical cabinets, agricultural and horticultural cabinets, collections for illustrations in mechanical and civil engineering, and a fine-art gallery, embracing over 400 casts of celebrated sculptures, a large collection of photographs and engravings from celebrated paintings, and a gallery of historical portraits. The library in 1880 included about 12,200 bound volumes and nearly 2,500 pamphlets. The corps of instructors at the same date included 17 professors, and 10 teachers and assistants. Number of students, 399; alumni, 227. The university is organized in four departments, viz.: literature and science, engineering, natural science, and agriculture. These embrace respectively the schools of ancient, English, and modern languages; mechanical, civil, and mining engineering, and architecture; chemistry, natural history, domestic sciences, and agriculture and horticulture. Women are admitted to all the courses of study. Military training, heretofore given to all male students, is hereafter to be confined to those of the first two years. There is a gymnasium for men and a calisthenic hall for women. J. M. Gregory, LL.D., regent, resigned in 1880, and S. H. Peabody, PH.D., is the acting regent.

ILLINOIS AND MICHIGAN CANAL, an artificial navigable water-course connecting lake Michigan and the navigable waters of the Illinois river, and allowing of the passage of vessels from the gulf of Mexico to the gulf of St. Lawrence by using also the Welland canal, which forms a navigable channel from lake Erie to the St. Lawrence river. In 1825 it was estimated that the canal, about 100 m. in length, would cost about $700,000. In 1833 new surveys and estimates were made placing the cost of a canal 40 ft. wide and 4 ft. deep at $4,043,000; but nothing definite was attempted till 1836, when the plan was altered and estimates were made for a canal 60 ft. wide at the surface, 36 ft. at the bottom, and 6 ft. deep, costing $8,654,000. Work was commenced in June, 1836, and continued till Mar., 1841, when it was discontinued for want of available funds. In 1845 an additional $1,800,000 was raised by the sale of lands owned by the canal. It must here be stated that in consequence of a change of plans the entire cost fell within the estimates which had been made, so that at the opening of the canal in April, 1848, the entire expenditure had been $6,170,226. When completed the eastern terminus joined the s. branch of the Chicago river, five m. from the mouth of the main stream. A direct line is pursued to the valley of the Des Plaines, the main eastern branch of the Illinois river, a distance of about 8 miles. It then traverses the valley to the mouth of the Kankakee river, a distance of 42 m., passing through the towns of Lockport and Joliet, and receiving water from four feeders, Calumet, Des Plaines, Du Page, and Kankakee rivers. The canal now follows the valley of the Illinois river to its terminus, La Salle, passing through the towns of Morris and Ottawa, receiving water from Fox river; the whole length being 96 miles. The water at La Salle is 145 ft. lower than lake Michigan, and the descent is accomplished by means of 17 locks, varying in lift from 3½ to 10 feet. The locks are 110 ft. long by 18 wide, giving passage to boats of 150 tons. One effect contemplated and secured by this great work has been the purification of the water in the Chicago river, formerly almost stagnant, with a scarcely perceptible current into lake Michigan, and retaining much of the sewage of the great city; but now flowing freely in the opposite direction toward the Mississippi and the gulf of Mexico.

ILLUMINATED MANUSCRIPTS. See MANUSCRIPTS.

ILLUMINATI, a name which has at different periods been borne by four different societies—that of the *Alombrados* in Spain, in the end of the 16th c.; that the *Guerinets* in France, about the year 1684, enthusiasts and visionaries; an association of mystics in Belgium, in the latter half of the 18th c.; and the *Order of the Illuminati*, which was founded at Ingolstadt on May 1, 1776, and soon spread over almost all the Roman Catholic parts of Germany. It is this which is now commonly meant when the name illuminati is employed. Its founder at first called it the order of the perfectibilists. It owed its existence to Adam Weishaupt, professor of canon law at Ingolstadt, a man of superior abilities and much benevolence, but deficient in practical knowledge of mankind. Filled with detestation of Jesuitism, and impatient of the restraints which were at that time imposed on the human mind in Roman Catholic Germany, and in no part of it more than in Bavaria, under the bigoted administration of the elector Charles Theodore, he conceived the idea of forming an association which should extend its ramifications everywhere, and should consist of the choicest spirits, should labor for the establishment of the dominion of reason, and promote religious and political enlighten-

ment and emancipation. Religious dogmas and forms of worship were to be rejected, a system of deism was to be propagated, and republican opinions. The accession of the Baron von Knigge to the new order, and the support which it received from the Freemasons, led to its rapid extension, so that, at one time, more than 2,000 of the most accomplished men in Germany were members of it. Weishaupt's knowledge of the order of the Jesuits led him to borrow some of their methods for the accomplishment of what he regarded as the most opposite ends; and the illuminati were soon involved in a system of mutual espionage, confession, and the like, essentially inconsistent with true freedom, but calculated to place the threads all in one hand, by which the holy legion was to be led on, as it was imagined, to the benefaction of mankind. But from this cause, the dissolution of the order soon ensued. Weishaupt and Knigge, its two leaders, quarreled with one another. The order began to be openly denounced as dangerous, and, on June 22, 1784, an edict was issued by the elector of Bavaria for its suppression, which was followed by another March 2, 1785. Weishaupt was degraded and banished. He retired to Halle, where he died in 1830, at the age of 83. Various other members were severely punished, and the form of justice was not strictly observed in the proceedings against them.—Great importance was at one time attached to the order of the illuminati, whose secret influence was regarded as a principal cause of many of the political events of the time of the French revolution, and the works of abbé Barruel and of prof. Robison of Edinburgh upon this subject were eagerly read, but the highly exaggerated character of their views is now generally acknowledged.

ILLUPIE. See BASSIA.

ILLUSORY APPOINTMENT, a legal phrase which denotes that where a person has a power or faculty to divide property among several others, such as children, and he gives one or more a very small sum, and the bulk of the property to the rest, the former is called an illusory appointment. In vulgar parlance, it is like cutting off an heir or child with a shilling. In general, it is competent, both in England and Scotland, to make an illusory appointment, but much depends on the peculiar terms of the deed or will originally giving this power to appoint or divide.

ILLUSTRATED PUBLICATIONS are a remarkable feature of the literature of our times. The employment of illustrations or pictorial sketches to render books more intelligible and attractive, has long been common, but has of late years been carried to an extent previously unknown. There are two methods of illustration: by copper or steel-plate engravings, which, being on leaves apart from the text, are executed separately; and by wood-engravings, which, inserted as blocks in the typography, are printed as part of the work. Wood-engraving is not new, but it was little employed for general illustration until comparatively recent times. Throughout the 18th and the first quarter of the 19th c., illustrations, for the most part, consisted of separate engravings on copper. See ENGRAVING. In the early part of the 19th c., books of travels and works of a fanciful kind, and also in natural history, issued in London, were illustrated chiefly by aquatint engravings. Among the artists who were noted for this species of illustration were Rowlandson, John Clark, and the Cruikshanks, and as the engravings were colored by hand, they were particularly attractive. Clark was principally employed to illustrate voyages and travels. In the preparation of designs for these illustrations, the author of the work was usually much indebted to the artist, who, in many cases, was furnished with only a few scratches to guide him in his representations. The use of aquatint engravings was at length superseded by lithography; but before this new species of illustration came greatly into vogue, wood-engraving took the place of all kinds of illustration except that of the high-class line steel-engravings, which are still in use for costly publications. The taste for illustrated works first sprung up in England, and thence it extended to France, Germany, and the United States. From 1820 to about 1830 was the great era of illustrated annuals (q.v.). The taste for these illustrated year-books ultimately wore itself out, and was succeeded by a demand for highly illustrated books of poetry by popular authors, such as Rogers, Byron, and Campbell, and in the disposal of these elegant works, some publishers realized handsome fortunes. Latterly, illustration has consisted for the greater part in wood-engravings, for they possess the inestimable advantage of being printed with the letter-press, and in the hands of high-class artists, the design and execution of these embellishments have reached extraordinary perfection. Executed with comparative cheapness and rapidity, wood-engravings have been largely employed to illustrate popular periodicals, encyclopædias, and newspapers. *The Illustrated London News*, which was the first, is still the leading illustrated paper; *The Graphic*, a more recent publication, is its chief rival. See WOOD-ENGRAVING.

ILLYRICUM (Gr. ILLYRIS, ILLYRIA) is the Roman name of a country whose limits in ancient times varied very considerably. In the 4th c. B.C. the Illyrians, who are the ancestors of the modern race generally known as Albanians (see ALBANIA), inhabited the whole eastern coast of the Adriatic sea and adjacent islands, with the western parts of Macedonia as far as Epirus. Philip of Macedon conquered the country as far as the river Drilon (modern Drino), and thence arose the division into *Illyris Græca* and *Illyris Barbara* or *Romana*. The former, now Albania (q.v.), was incorporated with Macedonia. *Illyris Barbara* or *Romana* was divided into Iapydia, Liburnia, and Dalmatia. The Illyrians were much addicted to piracy, which soon brought them into collision with the

Romans, and led to their subjugation about two centuries B.C. They made numerous efforts to shake off the Roman yoke, but were always defeated, and the country became a most important province of the Roman empire, comprising the territory represented in modern times by Croatia, Dalmatia, Herzegovina, Montenegro, nearly all Bosnia, and a part of Albania. On the division of the Roman empire Illyricum shared in the vicissitudes that followed that act. A decree of Napoleon, Oct. 14, 1809, gave the name of Illyrian provinces to Carniola, Dalmatia, and other countries from the Adriatic sea to the Save, then belonging to the French empire. At his fall, these provinces were united as a kingdom to the Austrian empire, and some alterations were made in its boundaries, especially by the restoration to Hungary of what had formerly belonged to it, and the annexation of the whole of Carinthia instead. The kingdom was divided into the two governments of Laibach and Triest, Laibach being the capital, which arrangement subsisted till 1849, when it was subdivided, for administrative purposes, into the duchies of Carinthia (q.v.), Carniola (q.v.), and the coast district, containing the counties of Görz (q.v.), Gradiska, and Istria (q.v.), with the city and territory of Triest (q.v.).

IL'MEN (formerly *Moysk*), a lake in n.w. Russia, government of Novgorod, 27 m. long, 20 m. broad, and 16 ft. deep. The lake is stormy, and unfit for navigation; its bottom stony. The rivers Shelon, Lovat, Msta, and several others, flow into the lake, which discharges its waters through the river Volkhof into lake Ladoga. The lake abounds in fish, chiefly sandres, bream, and smelt, and fishing on its banks occupies a population of about 20,000. The lake Ilmen is historically remarkable, because it was on its banks that the Slavonian tribes lived, who, a thousand years ago (862), invited the Variago-Russ to come and rule over them, from which time dates the origin of the Russian nation.

ILMEN'IUM, the name applied by Hermann to a new metal analogous to tantalum. He obtained its oxide from a mineral to which the various names of *urano-tantalite*, *samarskite*, and *yttro-ilmenite* have been applied, and which occurs in the Ilmen mountains in Siberia. Its existence as an independent metal is not satisfactorily established.

IL'MINSTER, a small but ancient market-t. of England, in the co. of Somerset, is situated on the right bank of the Isle, 44 m. s.w. of Bath. The free grammar and commercial schools, with an endowment of nearly £1000 a year, were founded in 1586. Some manufactures of woolens, silks, and lace are carried on. Pop. '71, 2,431.

IL OBEID', or EL OBEID (pronounced *Lobeid*), an important trading t. of Africa, capital of Kordofan, is situated in lat. 13° 11′ n., long. 29° 35′ e., at the foot of a long and gradually sloping plain, the drainage from which, after heavy rains, frequently inundates the principal streets. The town consists of a number of villages, originally separate, and inhabited by distinct races, but now joined together, and only distinct enough to form separate quarters. The houses and mosques, as well as the government offices, are almost all built of a fragile clay, and the general appearance of the place is uninviting, gloomy, and dirty. The *zoog*, or market-place, contains four rows of booths, and fruit, vegetables, tobacco, and manufactures in iron and wood are here sold. The wholesale trade is carried on in private houses. Gum-arabic, ivory, tamarinds, and ostrich feathers are the chief articles of export. Pop. estimated at about 30,000.

ILOPANGO, a lake of Central America, in the republic of San Salvador, of volcanic origin, 14 m. long, 6 m. wide. It is situated in a fertile and beautiful plain surrounded by high hills.

ILO'RI, ILO'RIN, or, more properly, ALORI, a very large t. of Africa, the great center of the Fulbe, in Yóruba, is situated in lat. 8° 30′ n., and long. 4° 33′ e., 46 m. s.w. of the banks of the Niger, and about 150 m. n.e. from the shore of the bight of Benin. Nothing very definite seems to have been published regarding it. Dr Barth, in conversing about Ilori with an intelligent native who had lived for a long time in Constantinople, was told that it was "without the least doubt larger than the latter city."

IL'SLEY, EAST, a small but ancient market t. of Berkshire, England, is situated in a secluded valley amid bleak and dreary downs, about 56 m. w. of London. It is remarkable chiefly for its sheep-markets, which are among the most important in the kingdom; 50,000 sheep have been known to be penned for sale here in one day. The ordinary sheep-fairs are held on every alternate Wednesday, from the Wednesday fortnight before Easter till July. The downs in the vicinity of the town are celebrated as training-grounds for race-horses. About a mile distant is the village of West Ilsley. Pop. '71, 608.

IMAGE-WORSHIP (Gr. *iconolatria*), the use, in public or private worship, of graven or painted representations of sacred persons or things, and especially the exhibition of honor, reverence, or worship to or towards such representations. This practice, in the various degrees of which it is susceptible, has formed, for many centuries, so fruitful a subject of controversy among Christians, that we think it expedient first briefly to detail the history of the use of images in Christian worship during the several periods, and secondly to state summarily the opposite views of this history which are taken by the two great parties into which Christians are divided on the question.

Neither in the New Testament, nor in any genuine writings of the first age of Chris-

tianity, can any trace be discovered of the use of statues or pictures in the worship of Christians, whether public or private. The earliest allusion to such representations is found in Tertullian, who appeals to the image of the Good Shepherd as engraved upon the chalices. A very curious pagan caricature of Christianity, of the very same age, lately discovered scratched upon the wall of a room in the palace of the Cæsars (see GRAFFITI), which rudely represents a man standing in the attitude of prayer, with outstretched hand, before a grotesque caricature of the crucifixion, and which bears the title "Alexamenus worships God," has been recently alleged by Catholics as an additional indication of at least a certain use of images among the Christians of the 2d century. The tombs of the Christians in the Roman catacombs, many of which are of a date anterior to Constantine, frequently have graven upon them representations of the dove, of the cross, of the symbolical fish, of the ship, of Adam and Eve, of Moses striking the rock, of Jonas, of Daniel in the lions' den, of the apostles Peter and Paul, and above all, of the Good Shepherd; and those compartments of the catacombs which were used as chapels are often profusely decorated with sacred representations, the age of which, however, it is not easy to determine with accuracy. But whatever opinion may be formed as to particular instances, such as these, it is admitted by Catholics themselves (who explain it by the fear of perpetuating the idolatrous notions of the early converts from paganism) that for the first three centuries the use of images was rare and exceptional; nor was it until after the establishment of Christianity under Constantine, and particularly after the condemnation of the Nestorian heresy in 430, that statues and pictures of our Lord, of the Virgin Mary, and the saints, were commonly introduced in churches, especially in the east and Italy. And yet, even in the 5th c., the practice had already reached a great height, as we learn from the church historian, Theodoret, for the east, and from Paulinus of Nola, for Italy; and in the 6th and 7th centuries many popular practices prevailed which called forth the condemnation of learned and pious bishops both in the east and in the west. It was usual not only to keep lights and burn incense before the images, to kiss them reverently, and to kneel down and pray before them, but some went so far as to make the images serve as godfathers and godmothers in baptism, and even to mingle the dust or the coloring matter scraped from the images with the eucharistic elements in the holy communion! This use of images by Christians was alleged as an obstacle to the conversion of the Jews, and as one of the causes of the progress of Mohammedanism in the east; and the excesses described above provoked the reaction of iconoclasm (q.v.). In the second council of Nice, 787, the doctrine as to the worship of images was carefully laid down. A distinction was drawn between the supreme worship of adoration, which is called *latreia*, and the inferior worship of honor or reverence, called *douleia;* and still more between *absolute* worship, which is directly and ultimately rendered to a person or thing *in itself;* and *relative*, which is but addressed *through* a person or thing, ultimately *to* another person or thing represented thereby. The second council of Nice declared, first, that the worship to be paid to images is not the supreme worship of *latreia*, but only the inferior worship of *douleia;* and, secondly, that it is not *absolute*, and does not rest upon the images themselves, but *relative*, that is, only addressed through them, or by occasion of them, to the original which they represent. This explanation of the doctrine and the practice was thenceforth generally received; but a strange error in the translation of the Greek acts of the council of Nice, by which it appeared that the same adoration was decreed by that council to images "which is rendered to the Holy Trinity itself," led to a vehement agitation in France and Germany under Charlemagne, and to a condemnation by a synod at Frankfort of the doctrines of the council of Nice. But an explanation of this error, and of the false transation on which it was based, was immediately afterwards given by the pope; and eventually the Nicene exposition of the doctrine was universally accepted in the western as well as in the eastern church.

At the reformation the reforming party generally rejected the use of images as an unscriptural novelty, irreconcilable as well with the prohibition of the old law as with that characteristic of "spirit and truth" which is laid down by our Lord as specially distinctive of the new dispensation: and they commonly stigmatized the Catholic practice as superstitious, and even idolatrous. The Zwinglian, and subsequently the Calvinistic churches, absolutely and entirely repudiated all use of images for the purposes of worship. Luther, on the contrary, while he condemned the Roman worship of images, regarded the simple use of them even in the church, for the purpose of instruction, and as incentives to faith and to devotion, as one of those *adiaphora*, or *indifferent* things, which may be permitted, although not of necessary institution; hence, in the Lutheran churches of Germany and the northern kingdoms, pictures, crucifixes, and other religious emblems are still freely retained. In the Anglican church the practice is still a subject of controversy. In the Presbyterian church, and in all the other Protestant communions, images are entirely unknown.

The Roman Catholic church, through the decree of the council of Trent, disclaims the imputation, commonly made against Catholics, of the idolatrous worship of images, "as though a divinity dwelt in them, or as though we [Catholics] asked anything of them, or trusted in them, as the heathens did in their idols." It renews the Nicene distinction between *absolute* and *relative* worship; the latter of which alone—"whereby we worship Christ and the saints, who are the prototypes of these images"—it sanctions or permits; and it contends for the great advantage, especially for the rude and unlearned

people, to be drawn from the use of pictures and statues in the churches as "memorials of the sufferings and of the mercy of our Lord, as instructive records of the virtues of the saints, and exhortations to the imitation of their example, and as incentives to the love of God and to the practice of piety" (Sess. xxv. *On the Invocation of Saints*). In many foreign churches, especially in Italy, in Southern Germany, and in France, are to be found images which are popularly reputed as especially sacred, and to which, or to prayers offered before which, miraculous effects are ascribed. But instructed Catholics declare that the legends connected with such images form no part of Catholic belief. Most Catholic books of instruction contain cautions against attributing such effects to any special virtue of the images themselves, rather than to the special faith, trustfulness, and fervor which are stirred up by their presence, and by the recorded examples of the mercy of God with which they are associated in the minds of the faithful.

IMAGINARY QUANTITY. In the working of many algebraic problems, it often happens that the root of a negative quantity must be extracted; if the root is odd, the operation can be performed (see INVOLUTION), but if even, the root can only be *formally* extracted, and is in consequence called an *impossible* or *imaginary* quantity. For instance, the cube root of -64 is not an imaginary quantity, for $-4\times-4\times-4=-64$, and therefore $\sqrt[3]{-64}=-4$; but the square root of -64 is an impossible quantity, for no possible quantity (whether it be $+$ or $-$) multiplied by itself can produce a negative quantity; similarly and *à fortiori*, the fourth root of -64 is an impossible quantity, and the same is true of all even roots. Imaginary quantities are, however, generally reduced to one denomination as multiples of $\sqrt{-1}$, in the following manner: $\sqrt{-64}=\sqrt{64\times-1}=\sqrt{64}\times\sqrt{-1}=8\sqrt{-1}$; and again, $\sqrt{-18a^5}=\sqrt{9a^4\times-2a}=\sqrt{9a^4}\times\sqrt{2a}\times\sqrt{-1}=3a^2\sqrt{2a}\sqrt{-1}$. These forms very frequently occur in higher algebra.

IMAGINATION. The meaning of this word enters into many relationships, and is thereby rendered difficult to define. The principal meaning is doubtless what connects it with poetry and fine art, from which the other significations branch off. The simplest mode of explaining this complicated relationship will be to state in separation the different constituents of the power in question. We shall then see why and where it touches upon other faculties, which still require to be distinguished from it.

1. Imagination has for its objects the *concrete*, the real, or the individual, as opposed to abstractions and generalities, which are the matter of science. The full coloring of reality is implied in our imagination of any scene of nature. In this respect there is something common to imagination and memory. If we endeavor to imagine a volcano, according as we succeed we have before the mind everything that a spectator would observe on the spot. Thus, sensation, memory, and imagination alike deal with the fullness of the actual world, as opposed to the abstractions of science and the reasoning faculties.

The faculty called *conception*, in one of its meanings, has also to do with this concrete fullness, although, in what sir William Hamilton deems the original and proper meaning of that word, this power is excluded. In popular language, and in the philosophy of Dugald Stewart, conception is applied to the case of our realizing any description of actual life, as given in history or in poetry. When we completely enter into a scene portrayed by a writer or speaker, and approach the situation of the actual observer, we are often said to *conceive* what is meant, and also to imagine it; the best word for this signification probably is "realize."

2. It is further essential to imagination in its strictest sense that there should be some original construction, or that what is imagined should not be a mere picture of what we have seen. Creativeness, origination, invention, are names also designating the same power, and excluding mere memory, or the literal reproduction of past experience. Every artist is said to have imagination according as he can rise to new combinations or effects different from what he has found in his actual observation of nature. A literal, matter-of-fact historian would be said to be wanting in the faculty. The exact copying of nature may be very meritorious in an artist, and very agreeable as an effect, but we should not designate it by the term imagination. There are, however, in the sciences, and in all the common arts, strokes of invention and new constructions, to which it might seem at first sight unfair to refuse the term in question, if originality be a leading feature in its definition. But still we do not usually apply the term imagination to this case, and for a reason that will appear when we mention the next peculiarity attaching to the faculty.

3. Imagination has for its ruling element some *emotion* of the mind, to gratify which all its constructions are guided. Here lies the great contrast between it and the creativeness of science and mechanical invention. These last are instrumental to remote objects of convenience or pleasure. A creation of the imagination comes home at once to the mind, and has no ulterior view.

Whenever we are under the mastery of some strong emotion, the current of our thoughts is affected and colored by that emotion; what chimes in with it is retained, and other things kept out of sight. We also form new constructions that suit the state of the moment. Thus, in fear, we are overwhelmed by objects of alarm, and even conjure up specters that have no existence. But the highest example of all is presented to us by the constructions of fine art, which are determined by those emotions called *æsthetic*, the sense of beauty, the pleasures of taste; they are sometimes expressly styled

"pleasures of the imagination." The artist has in himself those various sensibilities to an unusual degree, and he carves and shapes his creations with the view of gratifying them to the utmost. Thus it happens that fine art and imagination are related together, while science and useful art are connected with our reasoning faculties, which may also be faculties of invention. It is a deviation from the correct use of language, and a confounding of things essentially distinct, to say that a man of science stands in need of imagination as well as powers of reason; he needs the power of *original construction*, but his inventions are not framed to satisfy present emotions, but to be instrumental in remote ends, which in their remoteness may excite nothing that is usually understood as emotion. Every artist exercises the faculty in question if he produces anything original in his art.

The name "fancy" has substantially the meanings now described, and was originally identical with imagination. It is a corruption of fantasy, from the Greek *fantasia*. It has now a shade of meaning somewhat different, being applied to those creations that are most widely removed from the world of reality. In the exercise of our imagination we may keep close to nature, and only indulge the liberty of re-combining what we find, so as to surpass the original in some points, without forcing together what could not co-exist in reality. This is the sober style of art. But when, in order to gratify the unbounded longings of the mind, we construct a fairyland with characteristics altogether beyond what human life can furnish, we are said to enter the regions of fancy and the fantastical.

The "ideal," and "ideality," are also among the synonyms of imagination, and their usual acceptation illustrates still further the property now discussed. The "ideal" is something that fascinates the mind, or gratifies some of our strong emotions and cravings, when reality is insufficient for that end. Desiring something to admire and love beyond what the world can supply, we strike out a combination free from the defects of common humanity, and adorned with more than human excellence. This is our "ideal," what satisfies our emotions, and the fact of its so doing is the determining influence in the construction of it.

IMAUM', the appellation given to the most honored teachers of Mohammedanism. The word is Arabic, and signifies a director or teacher. It is commonly employed to designate any of the persons belonging to the Mohammedan ulema (q.v.), or priestly body. They are distinguished from the laity by a turban somewhat higher than usual. They are held in great reverence by the people. The sultan himself has the title of imaum, as the spiritual chief of all Moslems. The word is sometimes incorrectly written imaun.

IMAUS. See HINDÚ-KÚSH.

IMBATTLED. See EMBATTLED.

IMBECILITY must not be confounded with idiocy. In the former, there is the *imperfect* development of mind; in the latter, there is the *non*-development of mind. In the feeble intellect there may be present every faculty which distinguishes the most gigantic understanding, and these may act under ordinary laws, but they are dwarfed, incapable of continued growth and training, and are exercised and applied under the guidance and assistance of others, or of external circumstances. There are large numbers of weak-minded, useless persons in every community, who differ from the more robust intellects solely in degree. But the more marked and recognizable imbecility, as transmitted congenitally, as following dentition, chorea, convulsions, and diseases which retard vigorous bodily development, or as induced by the great constitutional changes at puberty, is characterized by all or many of the following symptoms. The expression is vacant, the senses are dull; the head is small, the body deformed; the gait is vacillating and restless; the head is pendent, thrown back, or agitated; the saliva escapes; the language is limited and infantile; the ideas are few, and consist of mere sensuous impressions; the temper is timid, facile, and vain; and the passions are little susceptible of control. The affection has been regarded as general, or involving the whole mind; or as partial, when the intellect only, or the sentiments only, or a particular faculty may be feeble and ineducable. In a legal view such persons have been divided into those who have, and those who have not, a moral perception of right and wrong. It is, however, worthy of consideration, that while they may know right from wrong in their ordinary and habitual range of duties, and within the scope of their own capacity, they may fail to do so beyond these narrow limits, and where questions of property, propriety, or abstract justice are concerned. Many imbeciles are muscular, capable of performing acts requiring strength and endurance rather than dexterity; and in this country, as well as many others, they are not merely the "naturals," who run everybody's messages, but they are converted into the domestic drudges of the homestead, the white slaves of the farm. From the more clever and cunning of the class were the professional fools of former ages selected. Imbeciles are often confounded with genuine idiots, and their partial educability has exaggerated the supposed success in the attempts to elicit and mature the embryo mind. However far this training may be carried, and even when the subject has become self-maintaining, it may be safely asserted that he is never self-guiding nor self-governing, nor capable of an independent existence.—Howe, *On the Causes of Idiocy*; Reports, Idiot School, Earlswood; *De l'Idiotie chez les Enfants*, par Felix Voisin.

IMBECILITY, in point of law—i.e., something short of idiocy or lunacy—is no ground of relief in England against a contract, though relief is always granted in case of fraud, and the imbecility of one of the parties may form an element of the fraud. Nor does the law of England in any peculiar way protect an imbecile person or his property; for so long as a person is not actually insane or an idiot, he can do what he likes with his own. In Scotland, however, an imbecile person is to a certain extent protected against being imposed upon, as regards his heritable property, by a step called interdiction, which consists in either the imbecile, who is conscious of his weakness, executing a bond of interdiction, by which he puts himself under trustees, whose consent is in future made necessary to render valid his contracts, or he may be judicially interdicted by the court of session, at the instance of his next of kin, with like effects. The trustees or guardians in such cases are called the interdicters. See LUNACY.

IMBER, or IMMER. See DIVER.

IMBERT, BARTHELÉMI, 1747–90; b. Nismes, France. His poem, *Le Jugement de Paris*, was for a time very successful, but with the exception of his *Choix d'Anciens Fabliaux*, 2 vols. in verse, none of his works are of much value.

IMBROS, an island of the Ægean sea, about 11 m. n.e. of Lemnos, and the same distance from the mouth of the Dardanelles. It is 18 m. in length, and has an area of 116 sq. miles. The island is mountainous, its highest summit being 1845 ft. above sea-level, and is covered with wood. Corn, wine, and cotton are abundantly grown in the valleys; oil is also produced. Imbros contains four villages, the chief of which, called Imbro, is built on the site of an ancient town of the same name. Pop. of entire island about 4,000.

IMBRU'ED, or EMBRUED, an expression used in heraldry to signify bloody, or dropping with blood. Weapons thus blazoned are drawn with drops of blood falling from them.

IMERI'TIA, formerly an independent Transcaucasian territory, now part of the government of Kutaïs (see TRANSCAUCASIA), is bounded on the n. by the Caucasian mountains, and on the w. by the districts of Ghuria and Mingrelia. Area, 4,040 sq.m.; pop. 100,000. Its history as an independent dominion commenced from about the beginning of the 15th c., and was long marked by internal dissensions. In 1745 Salomon I. was proclaimed, but his nobles revolting shortly after, and aided by the Turks, dethroned him. Salomon applied for help to Russia, and in 1769 Count Todtleben, at the head of a Russian force, entered Imeritia, restored the king, and drove back the Turks. The civil dissensions of this province, however, continued, and at last, in 1810, after having long acknowledged allegiance to Russia, it was formally incorporated in and proclaimed a province of that empire.

IMIDES. See ORGANIC BASES.

IMITA'TION. See SYMPATHY.

IMITATION, in the science of musical composition, is the repeating of the same passage, or the following of a passage with a similar one, in one or more of the other parts or voices, and it may be either strict or free. When the imitated passage is repeated note for note, and every interval is the same, it is called strict, and it may take place in the unison or octave, or in any other of the degrees of the scale, either above or below the original passage. The progression of a passage may also be imitated by an inversion, or by reversing the movement of the original; also by notes of a greater or of a lesser value. See DOUBLE COUNTERPOINT, FUGUE, and CANON. Imitation in composition is one of the most important means of producing unity and animation in the progression of the parts, and is used in a strict, and also in a free manner, in the instrumental works of Haydn and Beethoven, and also by Mozart in his easier operatic works. Many composers, however, resort to imitation improperly, and generally from poverty of musical ideas, or from pedantry. No fixed rules can be given for its use.

IMITATIVE INSANITY. There are many mental diseases, especially those marked by grotesque external manifestations, by gesticulations, and convulsive seizures, which appear to be propagated by imitation. In the healthy and naturally constituted there exists a tendency to copy and reproduce, or represent what powerfully impresses the imagination; and during the excitement of individuals or communities, this inclination is more influential, and passes beyond the control of the will. Great caution, however, must be exercised in distinguishing between what is epidemic and depends upon atmospheric or external moral causes, from the results of strong or morbid states of the mind itself. An idiot is mentioned by Gall, who, having seen the slaughter of a pig, killed a man after the same fashion. A child of seven years old suffocated a younger brother on the suggestion of the strangling of Punch at the hands of the devil. The example of suicide by hanging having been set by a pensioner in the Hôpital des Invalides, six similar deaths followed, and by suspension from the same lamp-post. After the return of the Bourbons, there appeared in succession seven female claimants to the parentage of Marie Antoinette; and pyromania, propagated by sympathy, is well known to have existed in Normandy in 1830.

IMMACULATE CONCEPTION OF THE BLESSED VIRGIN MARY, FEAST OF, a festival celebrated on Dec. 8th in the Latin, and on the 9th in the Greek church, in which latter

church it is held under the name of "The Conception of St. Anne," the mother of the Virgin Mary. The festival of the conception itself is traceable in the Greek church from the end of the 5th c., and in the Latin dates from the 7th; but a great controversy prevailed for a long time in the west as to whether and in what sense the conception of the blessed Virgin Mary was to be held immaculate, and in what sense the blessed Virgin herself was to be held conceived without sin. It was believed to be a consequence of the doctrine of the divine maternity, and a necessary part of the honor due to the incarnation, that the blessed Mother should be held to have been at all times free from the stain of sin. This might have been, either by her having been, like the prophet Jeremiah (Jer. i. 6), or the baptist St. John (Luke i. 35), sanctified before her birth—that is, purified in her mother's womb from the stain of original sin; or by the still higher sanctification of having been entirely exempted from the stain of sin, either—for the discussion was carried to all these subtleties—before the formation of the embryo in the womb of her mother, or at least before its animation by union with the soul. The actual controversy in the west may be said to have commenced with St. Bernard, who not only remonstrated with the canons of Lyons in 1131 for their unauthorized introduction of this festival in their cathedral, but rejected the opinion of the blessed Virgin's having been conceived free from original sin, though he admitted her sanctification in her mother's womb (*Epist.* 174, *Ad Canon. Lugdunensis*). The discussion thus raised led to a protracted controversy in the schools. The great master of scholastic subtlety, John Duns Scotus, in a disputation held before the university of Paris in 1307, maintained the doctrine of the immaculate conception in its highest sense; and the entire order to which he belonged, the Franciscan, as well as the school to which he has given his name, the Scotists, afterwards zealously defended it. On the other hand, the Thomist school, which was that of the Dominican order, having denied the immaculate conception, much division for a time existed; but the prevailing tendency was at all times towards the Scotist opinion. The university of Paris, in 1387, condemned the Thomist doctrine. The council of Basel, although, it is true, at the time when it was in conflict with the pope—declared the doctrine of the immaculate conception to be a Catholic dogma, and reprobated in the strongest terms the opposite opinion. Sixtus IV., however, imposed on the defenders of both opinions, in 1470, the obligation of mutual toleration and charity, and renewed this constitution in 1483; but in the end of the same century the university of Paris required, as a condition of the doctorate, an oath on the part of the candidate that he would defend the dogma of the immaculate conception. The council of Trent, without discussing the scholastic dispute, merely declared that "in its decree on original sin it did not comprehend the blessed and immaculate Virgin Mary," and renewed the constitution of Sixtus IV., already referred to. This abstinence on the part of the council led to a further renewal of the dispute, which reached such a pitch towards the close of the 16th c. that Pius V. not only prohibited either side from stigmatizing the opposite with the name of heretical, but forbade all public discussions of the subject, except in theological disputations in the presence of a learned auditory. In the pontificates of Paul V. and Gregory XV., earnest instances were made by the Spanish crown to obtain a definite declaration in favor of the doctrine of the immaculate conception; but the pope again refused, contenting himself with repeating the constitution of Sixtus IV. He added, however, certain new provisions: 1. That disputants, in asserting the doctrine of the immaculate conception, should abstain from assailing the opposite doctrine. 2. That no one except the members of the Dominican order, and others specially privileged, should presume to defend, even in private disputation, the doctrine that the blessed Virgin Mary was conceived in original sin. 3. That, nevertheless, in the public mass or office of the church no one should introduce into the prayers or other formularies any other word than simply *conceptio*, without adding any epithet involving either doctrine. At the same time, opinion was setting steadily in favor of the doctrine of the immaculate conception. Alexander VII., and afterwards Clement IX., added new solemnity to the festival. Clement XI. ordained that it should be observed as a holiday of obligation, and at length Gregory XVI. permitted that the epithet immaculate should be introduced into the public service. In the end, at the instance of bishops in various parts of the church, the late pope Pius IX. addressed a circular to the bishops of each nation, calling for their opinion, and that of their people, as to the faith of the church on the point; and on the receipt of replies all but absolutely unanimous, he issued a solemn decree at Rome, in a numerous council of bishops, on Dec. 8, 1854, declaring the doctrine to be an article of Catholic belief, and proposing it as such to the universal church. This decree has been implicitly accepted throughout the Roman church.

IMMANUEL. See EMMANUEL.

IMMERMANN, KARL LEBRECHT; 1796–1840; b. Germany. Though educated for civil service, and active in political matters in 1815, he devoted himself chiefly to poetry and the drama. His unsuccessful attempt to manage the Düsseldorf theater occasioned a heavy pecuniary personal loss. His tragedies and comedies, though of great merit, were not adapted to the stage. His most valuable work, *Münchhausen*, 4 vols., passed through several editions.

IMMIGRATION (EMIGRATION, *ante*) to the United States far exceeds that to any other country in the world. The steadily increasing current of human beings flowing

hither from the ends of the earth attracts universal attention and demands serious deliberation. There are traditions of the simultaneous migration of entire nations in the early ages, but never since the dispersion at Babel has there been anything of such general and cosmopolitan nature as that which forms one of the great phenomena of the age—American immigration. Before the revolution there were few immigrants. The earliest were the gold-seekers from Spain, but they had no intention of remaining in the country. The moving causes of immigration to Canada and New England were religious and political troubles. The Puritans came for religious freedom. The revocation of the edict of Nantes drove a great number of Huguenots across the sea. Yet before the Revolution the extent of immigration was not significant. The establishment of a free republic brought a change, and Europe began to send forth her thousands; but they were as nothing when compared with the myriads of modern times. Up to 1820 no official records of immigration were kept. It was reckoned that from 1784 to 1794 the arrivals were not more than 4,000 per year. In 1794, owing to war between England and France, the arrivals reached about 10,000; but this was an exceptional year, and the number of arrivals was not again so large until 1807. Dr. Seybert, in his *Statistical Annals of the United States*, says the average of immigration from 1790 to 1810 was about 6,000 a year. During the decade 1806-16 immigration was almost suspended in consequence of war with England and serious political complications with France. England's doctrine—relinquished only after a war—"Once a subject, always a subject," was sufficient to deter most people from attempting to leave that country while the war was going on. The blockading of the French ports under the British orders in Council, Jan., 1807, and Napoleon's prompt retaliation in the Berlin decree of the same year, which interdicted commerce with Great Britain, followed by the Milan decree against all continental intercourse with the British, were other powerful influences to check and indeed practically destroy European emigration. The French decrees were annulled in 1811, just before the war between the United States and Great Britain, and American ships were released by France only to fall into the clutches of British cruisers. During the three years of war immigration was suspended, the arrivals being so few as to be hardly worth noticing. It was not until 1817 that the current of immigration, checked ten years before, began to flow freely, and in that year the arrivals, including American citizens coming home, were 22,240, nearly three times as many as in the preceding year. Great suffering occurred in ships crowded with immigrants, and the attention of congress was drawn to the subject. In the spring of 1818 a bill was proposed to remedy the evils; it was passed in Dec., and approved Mar. 2, 1819. In compliance with this act collectors of customs have ever since reported to the treasury department the number of passengers from other countries arriving in their several districts, with the sex, ages, and occupations of such passengers, and the countries in which they were born.

The following table gives the aggregates of immigration at all ports, from the organization of the government to Jan., 1880:

NUMBER OF ALIEN PASSENGERS ARRIVED IN THE UNITED STATES FROM FOREIGN COUNTRIES, FROM OCT. 1, 1819, TO JUNE 10, 1880.

PERIOD.	Alien Passengrs Arrived.	Immigrants arrived.	Excess of Immigr'nts over emigrants.	PERIOD.	Alien Passengrs Arrived.	Immigrants arrived.	Excess of Immigr'nts over emigrants.

Statistics of the sex and ages of immigrants are not complete, but, as the proportions do not vary in any perceptible degree from time to time, the figures of a single year will represent the average. They are:

Male adults	146,223	49.63 per cent of all immigration.
Female adults	86,089	29.23 per cent.
Children under twelve years	60,532	20.55 per cent.
Unascertained	1,637	.59 per cent.
Total	294,581	100.00 per cent.

The following table denotes the sexes and ages of immigrants from 1820 to 1860, inclusive:

Ages.	Males.	Females.	Total.	Per Cent. Male.	Per Cent. Female.
Under 5	218,417	200,676	419,093	4.14	3.81
5—10	199,704	180,606	380,310	3.79	3.42
10—15	194,580	166,833	361,413	3.69	3.16
15—20	404,398	349,755	754,093	7.67	6.63
20 and under	1,017,069	897,890	1,914,909	19.29	17.02
20—25	669,853	428,974	1,098,827	12.71	8.13
25—30	576,822	269,554	846,376	10.94	5.11
30—35	352,619	163,778	516,397	6.69	3.12
35—40	229,468	114,165	353,633	4.54	2.16
40 and over	342,022	200,322	542,344	6.49	3.80
20 and over	2,180,774	1,176,793	3,357,577	41.37	22.32
Total	3,197,823	2,074,663	5,272,486	60.66	39.34

It is worthy of note that of all immigrants 64 in every 100 are in the reproductive age. This accounts for the often-noticed fact that foreigners are, or appear to be, more prolific than natives. An examination of the census shows that nearly 45 per cent of male immigrants are between the ages of 20 and 40; while of male natives, 14½ per cent are within that period. There is, in fact, but slight difference in the proportion of children to mothers between natives and foreigners. In the New York census of 1865 it was shown that the average number of children to native mothers was 341 in 100, while for foreign mothers it was 360 per 100.

The nationality of immigrants has, of late years, been very carefully recorded, especially at New York, where nearly 77 per cent of the strangers are landed. The following table will show where the greater portion of the vast multitude came from:

Ireland	3,065,761
England	894,444
Scotland	159,547
Wales	17,893
Other British	560,237
Total from British islands	4,697,912
Germany	3,081,813
Sweden	177,664
Norway	128,428
Denmark	48,630
Holland	44,319
Belgium	23,267
Mainly Teutonic	3,504,110
France	313,700
Switzerland	83,709
Italy	69,559
Spain	28,091
Portugal	9,062
Latin races	504,121
Russia	38,028
Poland	14,231
Hungary	6,085
	58,344

Hungarians are often counted as Austrians. Some thousands and hundreds from other European nations make up the greater part of the remainder.

The Chinese arrivals up to 1877 numbered 207,270; but probably not more than 100,000 have ever been in the country at one time. The whole number of countries and islands from which immigrants have been received is nearly seventy. A general summary for nine years is here given:

From Europe.....	264,548	351,265	396,380	261,232	181,635	120,103	105,092	100,832	133,070	1,914,157
From Asia.....	7,236	7,825	20,326	13,857	16,498	22,943	10,640	9,014	9,660	117,999
From Africa.....	43	62	39	22	54	54	22	14	17	327
From America	48,840	42,205	40,337	35,339	26,642	24,686	24,065	27,204	33,025	302,343
From Pacific Isl'ds.	25	2,416	1,413	1,170	1,269	1,312	914	606	816	9,941
From all others, not specified	658	1,033	1,308	1,719	1,400	888	1,124	799	1,238	10,167
Aggregate.....	321,350	404,806	459,803	313,339	227,498	169,986	141,857	138,469	177,826	2,354,934

As New York is the main port of debarkation for immigrants, that state in 1847 established a board of commissioners of immigration, through whose care nearly 8,000,000 immigrants have passed. A strong effort has been made in congress to take the control of immigration into the care of the general government, but thus far without success.

The destination of immigrants has been inquired for by the New York commissioners since 1854, with the following results:

Eastern States.	Number.
Maine	6,437
New Hampshire	4,326
Vermont	6,454
Massachusetts	179,233
Rhode Island	36,224
Connecticut	71,132
Total Eastern States	303,806

Nearly all who go east are employed in manufactories.

Middle States.	Number.
New York	1,572,542
New Jersey	123,361
Pennsylvania	402,491
Maryland	28,286
Delaware	3,514
Total Middle States	2,130,194

The great number under "New York" includes many of those who have not determined upon a place for final settlement.

Middle Western States.	Number.
Ohio	201,016
Michigan	109,290
Indiana	48,822
Illinois	365,926
Wisconsin	191,656
Total Middle Western	916,710

West of the Mississippi.	Number.
Minnesota	73,369
Iowa	85,369
Missouri	71,297
Kansas	23,572
Nebraska	22,459
Colorado	3,250
Total	279,316

Pacific States and Territories.	Number.
California	54,987
Oregon	945
Nevada	2,308
Territories	48,201
Total	106,441

Of the total for territories, Utah took 40,317—all Mormons.

Southern States.	Number.
Virginia	10,691
District of Columbia	11,597
West Virginia	1,806
North Carolina	1,058
South Carolina	2,806
Georgia	3,212
Florida	814
Alabama	1,016
Louisiana	6,888
Texas	5,415
Arkansas	922
Mississippi	1,362
Tennessee	6,746
Kentucky	17,112
Total	71,445

This makes a total of 3,807,715. The remainder went: 74,353 to the British provinces, 2,358 to Mexico, South America and elsewhere, and 22,759 gave no destination; the grand total of whom inquiries were made was 3,906,985. Of those settling in the United States, 5.35 per cent went to New England; 55.59 per cent to the Middle states; 24.07 per cent to the middle Western states; 7.33 per cent to west Mississippi states; 2.79 per cent to Pacific states and territories; and 4.87 per cent to the Southern states. The latter section of the union does not appear to be any more attractive to immigrants than it was in the days of slavery.

Many calculations have been made as to the amount of money brought into the country by immigrants, and the lowest places it at $50 per head. This would make near $500,000,000 for the whole. But there is far more value in the labor and enterprise which they bring.

The main causes of advance or decline in immigration are usually war, famine, or financial depression. The *coup d'etat* of Dec., 1851, within the three following years sent half a million persons to the United States. The Franco-German war had a similar effect, to a large extent. The Irish famines drove a million of the people of that island to this country. On the other hand, a financial crisis or a war in the United States at once checks immigration, as was seen after the panics or hard times of 1837, '57, '73, and '77. The rebellion naturally kept foreigners away, and the arrivals dropped from 153,640 in 1860 to 91,823 in 1861. The return of prosperity in 1879 started the tide again, and the year 1880 shows a total of nearly half a million of immigrants.

IMMORALITY, in point of law, is a good defense to actions and suits, but it must be some immorality which runs counter to the well-known policy of the law. Thus, for example, if a man gave a bond, or granted a deed, giving to a woman some annuity, with a view to induce her to live in concubinage, this would be a good defense against the bond or deed being enforced, for the law discountenances his conduct; whereas, if it were merely a bond, or a gift, in consideration of something of the same kind past and ended, the deed would be good. So the keeper of a house of ill-fame is not allowed to sue, and has no legal remedy against her guests for any sum agreed to be paid for immoral purposes. In most other respects the mere personal immorality of the parties who are litigants makes no difference whatever as to their respective remedies, for the law protects the bad as well as the good, the unjust as well as the just.

IMMORTALITY is the continued existence of the human soul in a future and invisible state. "If a man die, shall he live again?" is a question which has naturally agitated the heart and stimulated the intellectual curiosity of man, wherever he has risen above a state of barbarism, and commenced to exercise his intellect at all. The religion of all civilized peoples may be said more or less to recognize the affirmative of the question,* although often under very vague and materialistic forms. In the ancient Egyptian religion the idea of immortality first assumes a definite shape. There is a clear recognition of a dwelling-place of the dead and of a future judgment. Osiris, the beneficent god, judges the dead, and "having weighed their heart in the scales of justice, he sends the wicked to regions of darkness, while the just are sent to dwell with the god of light." The latter, we read on an inscription, "found favor before the great God; they dwell in glory, where they live a heavenly life; the bodies they have quitted will forever repose in their tombs, whilst they rejoice in the life of the supreme God." Immortality is plainly taught, but bound up with the idea of the preservation of the body, to which the Egyptians attached great importance, as a condition of the soul's

* Some of the most widely spread forms of belief in the world would seem to be exceptions to this statement: for in Hinduism the goal sought is absorption into the universal spirit, and therefore loss of individual existence; while the pious Buddhist strives for *Nirvana* or complete extinction. Yet even here the belief in a future life exists in the form of the transmigration of souls (q.v.).

continued life; and hence they built vast tombs, and embalmed their bodies, as if to last forever. In the Zoroastrian religion the future world, with its governing spirits, plays a prominent part. Under Ormuz and Ahriman there are ranged regular hierarchies of spirits engaged in a perpetual conflict; and the soul passes into the kingdom of light or of darkness, over which these spirits respectively preside, according as it has lived on the earth well or ill. Whoever has lived in purity, and has not suffered the *dêvs* (evil spirits) to have any power over him, passes after death into the realms of light. In the early Grecian paganism hades, or the realms of the dead, is the emblem of gloom to the Hellenic imagination. "Achilles, the ideal hero, declares that he would rather till the ground than live in pale elysium." This melancholy view of the future everywhere pervades the Homeric religion. With the progress of Hellenic thought a higher idea of the future is found to characterize both the poetry and philosophy of Greece, till, in the Platonic Socrates, the conception of immortality shines forth with a clearness and precision truly impressive. In the *Apology* and the *Phædo* Socrates discourses of the doctrine of the soul's immortality, in language at once rich in faith and in beauty. "The soul, the immaterial part, being of a nature so superior to the body, can it," he asks in the *Phædo*, "as soon as it is separated from the body, be dispersed into nothing, and perish? Oh, far otherwise. Rather will this be the result. If it take its departure in a state of purity, not carrying with it any clinging impurities of the body, impurities which during life it never willingly shared in, but always avoided, gathering itself into itself, and making the separation from the body its aim and study—that is, devoting itself to true philosophy, and studying how to die calmly; for this is true philosophy, is it not?—well, then, so prepared, the soul departs into that invisible region which is of its own nature, the region of the divine, the immortal, the wise, and then its lot is to be happy in a state in which it is freed from fears and wild desires, and the other evils of humanity, and spends the rest of its existence with the gods."

It is only in Christianity, however, that this higher life is clearly revealed as a reward not merely to the true philosopher, but to every humble and pious soul. Christ "hath brought life and immortality to light by the gospel." "According to his abundant mercy, God hath begotten us again unto a lively hope by the resurrection of Jesus Christ from the dead, to an inheritance incorruptible and undefiled, and that fadeth not away, reserved in heaven." It is undoubtedly owing to Christianity that the doctrine of the soul's immortality has become a common and well-recognized truth—no mere result of speculation, nor product of priestly invention—but a light to the reason, and a guide to the conscience and conduct. The aspirations of philosophy, and the conceptions of mythology, are found in the gospel transmuted into an authoritative influence, governing and directing the present life.

IMMORTALITY, *ante*. I. *Arguments for the fact.* 1. As matter does not cease to exist when it changes its form, so man's spiritual substance at least will not be annihilated when it changes its state: this argument, though not proving personal immortality, prepares the way for its proof. 2. The spirit, as in its nature, distinct from matter, will—we must suppose in lack of proof to the contrary—continue its existence; there is no proof that man's spirit dies; all that is known to die is his body; we must therefore believe his spiritual life to continue. 3. The mental powers, being capable of a development which cannot be reached in this life, must find in the future that unlimited sphere of exertion for which they have wisely been adapted. 4. The wisdom of God will complete what it has begun; his goodness will satisfy the longings of man's spiritual nature; his justice will bring to an end the present disorders of the moral world. 5. Our moral nature prompts the expectation that virtue and right will be rewarded, and vice and wrong punished or repressed in another world, as they are not fully in this. 6. In the history of mankind there has been a general belief in future rewards and punishments. In the Veda of the Hindus, Müller says: "The immortality of the soul, as well as personal responsibility after death, is clearly proclaimed." This statement prof. Roth confirms, saying: "We find in the Veda, not without astonishment, beautiful conceptions on immortality expressed in unadorned language with child-like conviction." The Chinese show their belief in immortality by worshiping their ancestors. When a man dies, they say he has returned to his family. Confucius taught that the spirits of the good are allowed to revisit their earthly habitations to receive homage and to bestow blessing. The Egyptians believed in a dwelling-place of the dead and a future judgment. "Osiris judges the dead, and having weighed their heart in the scales of justice, sends the wicked into darkness and the just to the god of light." According to Persian belief, man passed to a future of reward or penalty. Some tribes of South American Indians believe that there are two great powers of good and evil and a number of inferior deities who have been the creators of different families; and that when an Indian dies his soul goes to live with the deity who controls his particular family. Another American tribe "expect, when they die, to return to the original seat of their forefathers; the good reaching it by means of the intervening lake, which the wicked, burdened with their sins, cannot cross." The Choctaws are said to "hold that the spirit lives after death and must travel a great distance towards the west, and across a dreadful, deep, and rapid stream upon a long and slippery log. The good pass it safely, but the wicked slip and fall." The native tribes of Australia believe that all good men,

who are properly buried, at their death enter heaven, which, they say, is "a delightful place, the abode of two good divinities with an abundance of food, a pleasant climate, freedom from evil spirits, and pleasures suited to their tastes. They believe also in an evil spirit, who dwells in the nethermost regions." "The Greenlander believes that at death the soul travels to a land of perpetual summer, all sunshine and no night. But the journey is difficult and attended with many perils, in some of which the soul, suffering another death may perish utterly, to exist no more." Several nations in Java and America have, it is said, the idea of a perilous bridge which has to be crossed at death; while in Polynesia some think the soul, instead of crossing a bridge, must pass over a great gulf in a canoe. Among the more cultivated ancient nations nobler ideas of immortality were sometimes cherished. Homer represents Achilles as convinced of the existence of souls after death by the appearance to him of the dead Patroclus in a dream. Plato describes Socrates as arguing and declaring the sure immortality of the spirits of good men, and, it would seem, of all men—though only the pure could be happy. The Old Testament Scriptures undeniably refer to the fact of a future life, though they give only an incomplete revelation concerning it. Of Enoch they say, "He was not, for God took him." Abraham, they say, "died and was gathered to his fathers," referring, not to his burial, for he was not buried near their graves, but to his entrance into the future state. So Jacob was gathered to his people when he died, though his burial was delayed many days. So Aaron was gathered to his people, though he was buried on Mount Hor; and Moses also, though no man knew of his sepulcher. Abraham, with other Old Testament believers, desired a heavenly country and "looked for the city which hath the foundations." David said, "I shall be satisfied when I awake with thy likeness." 7. Christ and the New Testament bring life and immortality to light, certifying what had been doubtful and dim. Christ stands as the supreme and final witness to the fact.

II. *Its nature and extent.* Of its nature we know little, since reason has not the materials for a science of immortality, and revelation is silent except as concerns the moral and practical bearings of the great fact which it affirms with intense energy. What is known through reason or revelation on this theme may be summed up as follows: 1. There is a life for man after the death of the flesh, which life is spiritual, in a spiritual body, amid spiritual surroundings. 2. This life is in the completed likeness of the life of Christ, who is the Son of God and the Head of humanity; therefore a life of blessing, beauty, and glory, of wisdom, power, and holy love—imperishable, incorruptible, eternal: to it pertain consciousness, identity, and a complete moral and spiritual personality. 3. This immortality is naturally possible to every individual person of the human race; being provided and secured in the very creation of the human race in and through the Son of God as the archetype of humanity, so that through him all men are constituted by their nature sons of God. 4. This immortality, naturally possible, becomes actual in the case of every human person who does not through willful love of evil refuse the eternal life of purity, holiness, and love: thence it becomes actual through Christ in the case of any heathen who sincerely and faithfully seek after God and goodness in the use of such light as they have: thence also it may be considered as applying to infants devoid of willful and personal wickedness. 5. This life, naturally possible to all men, does never become actual in the case of any who willfully refuse the light, and so reject the life. 6. These are not presented in the Bible as having immortality, or as entering into the eternal life, since immortality means deathlessness, and they are presented as under the power of death; yet to assert that they have no continued or future existence of any kind is to assert what no man knows or can prove: on the contrary, their future existence, certainly for a time, is indicated; and its everlasting continuance cannot, to say the least, be disproved. Thus, in fine, immortality, or the eternal life of a human spirit joined to the life of God, our thought can take firm hold upon; it is positive, radiant, unquestionable; while as to the eternal death, it is an "outer darkness" with no firm foothold for our thought as to its nature or its scenes. Upon these points, therefore, it is wise to restrict dogmatic assertion. See ESCHATOLOGY.

IMMORTELLES. See EVERLASTING FLOWER.

I'MOLA (anc. Forum Cornelii, or Forum Syllæ), a t. of Italy, in the province of Bologna, stands in a fruitful plain adjoining picturesque hills, close to the river Santerno, and 24 m. w.s.w. of Ravenna. It contains some fine palaces, churches, theaters, and benevolent institutions. Imola possesses some good manufactures of wax, oil, majolica, silk, and glass, besides extensive leather-curing establishments, and brick and tile works. From a species of white grape grown in the vicinity the delicious wine known as *vin santo* is manufactured. Pop. '72, 18,398.

IMOS'CHI, a t. of the Austrian empire, in Dalmatia, in n. lat. 43° 30', e. long. 17° 15'. It has markets twice a week, which are much frequented by Turks. Pop. (probably including a district), 22,000.

IMPALE, in heraldry, to arrange two coats of arms side by side in one shield divided per pale. It is usual thus to exhibit the conjoined coats of husband and wife, the husband's arms occupying the dexter side or place of honor, and the wife's the sinister

side of the escutcheon. When a man marries a second wife, heralds say that he may divide the sinister half of the shield per fess into two compartments, placing the family arms of his deceased wife in chief, and of his second wife in base. A husband impaling his wife's coat with his own is not allowed to surround the former with the collar or insignia of any order of knighthood to which he may belong. Bishops, deans, heads of colleges, and kings-of-arms, impale their arms with their insignia of office, giving the dexter side to the former. In early heraldry, when two coats were represented in one shield side by side, only half of each was exhibited, an arrangement which has been called *dimidiation*. Sometimes the one coat only was dimidiated. A reminiscence of dimidiation is preserved in the practice of omitting bordures, orles, and tressures in impaled arms on the side bounded by the line of impalement.

IMPANATION (Lat. *in*, and *panis*, bread), a technical word employed in the eucharistic controversies to express the peculiar opinion propounded by Luther as to the nature of the presence of Christ in the eucharist. Differing from the Roman Catholics in denying the transubstantiation of the bread and wine, and from the sacramentarians in denying that our Lord's presence was merely typical or figurative, Luther contended that the body and blood of Christ were present in, or along with, the elements of bread and wine; in a manner analogous to that in which the divinity of Christ co-exists in the same person with his human nature. Hence, by an analogy with the word incarnation, he devised for the eucharistic union the term impanation. This doctrine was the subject of a lengthened controversy with Zwingli at Marburg in 1529, which left each party unconvinced; and this theory still continues to be the received one in the orthodox Lutheran schools.

IMPEACHMENT, the name given to an accusation and trial of a peer or member of parliament, or, indeed, any other person, before the high court of parliament, for treason, or some high crime or misdemeanor. This is a kind of trial which is reserved for great and enormous offenders, particularly in matters affecting the constitution, for the ordinary tribunals generally suffice for all cases of crimes. Impeachment, accordingly, is of rare occurrence, the last instance being that of lord Melville in 1805; but as it is one of the high prerogatives of parliament to try offenders in this way, it is still competent to use it. The proceedings nearly resemble an ordinary trial at law. A pardon by the crown is not pleadable in bar of the prosecution, though, after sentence, the crown may pardon the offender. See May, *On Parliaments*.

IMPEACHMENT (*ante*). By the constitution of the United States, art. 1, sec. 4, the president, vice-president, and all civil officers of the nation, are made liable to removal from office on impeachment for and conviction of treason, bribery, or other high crimes and misdemeanors. The house of representatives has the sole power to initiate proceedings in cases of impeachment. When that body has impeached an officer it becomes the sole duty of the senate to try the case as thus presented, and when sitting for that purpose the members must be on oath or affirmation. When the president of the United States is tried the chief-justice must preside, and no person can be convicted without the concurrence of two-thirds of the members present. Judgment in cases of impeachment extends no further than removal from office, and disqualification to hold and enjoy any office of honor, trust, or profit, under the United States; but the party convicted is liable and subject to indictment, trial, judgment, and punishment, according to law. The chief trials for impeachment have been those of judge Chase in 1804, judge Peck in 1831, judge Humphreys in 1862, and president Johnson in 1868. Proceedings on impeachment under the state constitutions are somewhat similar. A witness giving testimony in a court of law is said to be impeached when he is proved to be unworthy of credit.

IMPEACHMENT OF WASTE, an expression in English law, used in deeds or wills. When an estate is given to a person for life, or for a term of years, *without impeachment of waste*, the tenant is entitled to cut timber, and do many things on the estate which otherwise he would be unable to do. Still, he is not allowed to do what he likes, for if he abuses his power, and attempts to cut down ornamental timber, for example, or deface the family mansion, the court of chancery will interfere by injunction to prevent this. The phrase is not used in Scotland, but the law is not materially different.

IMPENNATES, a name which has been applied to a tribe of swimming birds with very short and small wings, upon which there are only rudimentary feathers or scaly skin. The penguin and the great auk are examples. These birds are usually embraced in the family *brevipennatæ*, which includes penguins, auks, guillemots, divers or loons, and grebes. They belong to the order *natatores*. See PENGUIN, AUK, DIVER, GREBE and GUILLEMOT, *ante*.

IMPENETRABILITY, one of the essential properties of matter, implies that no two bodies can at the same time occupy the same space. If a nail be driven into a piece of wood it does not, properly speaking, *penetrate* the wood, for the fibers are driven aside before the nail can enter. If a vessel be filled with fluid, and a solid body be then placed in it, as much water will run over as is equal in bulk to the solid body, in

this way making room for it. The lightest gases are really as impenetrable as the densest solid; although, owing to their compressibility, it is not readily made apparent.

IMPERATIVE, CATEGORICAL. According to Kant (q.v.), man, in the consciousness of his moral liberty, recognizes two great laws regulating his will; the first prompts him to seek his own well-being, the second *commands* him to be virtuous, even at the sacrifice of that. From this opposition in his moral nature between desire and conscience, springs up the idea of duty, which, in the Kantian terminology, is called the "moral imperative," to which Kant adds the epithet *categorical*, to indicate that its commands are absolute and unconditional.

IMPERA'TOR. See EMPEROR, *ante*.

IMPERIAL CROWN properly signifies the crown borne by the German emperor; in form, a circle of gold, adorned with precious stones and *fleurs-de-lis*, bordered and seeded with pearls, and raised in the form of a cap voided at the top like a crescent. From the middle of the cap rises an arched fillet enriched with pearls, and surmounted by a globe, on which is a cross of pearls. The name imperial crown is, however, in English heraldry, applied to the crown worn in times past by the kings of England. From the 12th c. onwards the crown of the English sovereigns underwent repeated changes in form and enrichment. That of Edward II. was formed of four large and four small strawberry leaves, rising in curves from the jeweled circlet, and having eight small flowers alternating with the leaves. In Henry IV.'s crown eight strawberry leaves, and as many *fleurs-de-lis* alternated with 16 small groups of pearls, three in each. Under Henry V. the enriched circlet was for the first time arched over with jeweled bands of gold, and the apex of the arches surmounted with a mound and cross, while *crosses patées* were substituted for the strawberry leaves, and roses or *fleurs-de-lis* for the clusters of pearls. The arches, at first numerous and elevated to a point, became, in later times, restricted to four, and depressed in the center. The imperial crown of heraldry, as now understood, is, in point of fact, the form of crown worn by the English sovereigns from Charles II. to William IV. It has four *crosses patées* and four *fleurs-de-lis* set alternately on the circlet, while four pearl-studded arches, rising from within the crosses, carry at their intersection the mound and cross. The state crown of queen Victoria differs considerably from this, having a far more enriched character. It is covered with diamonds and studded with gems, and the arches are wrought into wreaths of rose, thistle, and shamrock formed of brilliants. A charge, crest, or supporter, crowned with a regal crown, is said to be *imperially crowned*.

IMPE'RIUM is a word used in the Roman law in various senses, the most important of which is that which it bears when applied to consuls and proconsuls—thence called imperators. Most of the superior magistrates were also intrusted with the imperium, which meant a sovereign authority. It is of very little practical importance in modern times to trace the extent or precise nature of the authority thus designated, as the subject has no bearing on modern law.

IMPERTINENCE, in English law, means some irrelevant matter introduced in an affidavit or pleading; and the court will generally order it to be struck out, and the offending party to pay the costs of doing so.

IMPETI'GO, a disease of the skin. It consists of crops of pustules, which may either be scattered or collected in groups. These pustules burst, dry up, and become covered with scabs or crusts of a yellow color, not unlike little masses of candied honey. From beneath these crusts, a purulent discharge commonly takes place; the crusts become thicker and larger, and the skin around and beneath them is red and raw. The disease may be either acute or chronic. In the former case, it is attended with febrile symptoms, which must be combated by the internal administration of purgatives and alkalies, strict attention to diet, and weak alkaline lotions. In chronic cases the discharge may be checked by a lotion containing 10 or 15 grains of oxide of zinc in an ounce of rose-water.

There are various forms of this complaint, as *I. figurata*, *I. sparsa*, etc. The disease known as *crustea lactea*, which sometimes covers the faces of children like a mask, is a sort of compound of impetigo and eczema; and the rose-water lotion already mentioned is a useful application for it.

IMPEYAN, or IMPEYAN PHEASANT, *Lophophorus Impeyanus*, a large gallinaceous bird of the family *phasianidæ*, a native of high cold regions of the Himalayas, but remarkable as much as any tropical bird for the splendor of its plumage, enhanced by the changing metallic tints which it exhibits—green, steel-blue, violet, and golden bronze. The fine plumage, however, belongs to the male alone. The female is clothed in sober brown, mottled with gray and yellow, and is smaller than the male. The impeyan has been found capable of domestication, and may probably be found capable of naturalization, in Britain. It derives its name from lady Impey, who first attempted to bring it alive to Britain, but failed. The Nepaulese name, *monaul*, signifies *bird of gold*.

IMPLEMENT, in Scotch law, means fulfillment of a contract or decree of the court.

IMPLEMENTS, AGRICULTURAL. Under this term are generally comprehended not only the implements used in the actual cultivation of the soil, but those requisite for other operations of farming, and for the preparation of the produce of the land for use, in so far as it is ordinarily carried on by the farmer. The first implements for the cultivation of the ground were doubtless such as could be used by man's unaided strength, and many such are still in use, as the spade, the hoe, the fork, and the shovel. When animals were reduced to the service of man the plow appeared in its first rude form. Grubbers, cultivators, etc., are recent inventions; rollers are more ancient. Sowing machines or drills are modern, but the harrow is ancient, although branches of trees drawn along the newly sown land, long served the purpose of its now carefully adjusted tines.—The necessity of irrigation in some countries early led to expedients and implements for accomplishing it. Implements for clearing the ground of weeds, for occasional stirring of the ground whilst under crop, and for *earthing up* crops, are all, except the hoe, of comparatively recent invention. The scythe and sickle have existed from remote antiquity, although the reaping-machine is a novelty only beginning to assume a very important place. Wheel-carriages of various descriptions and for various purposes must be mentioned among agricultural implements; also implements for thrashing and winnowing corn, for scutching and breaking flax, for ginning cotton, for crushing sugar-cane and evaporating its juice, etc. The preparation of the produce of different plants requires implements of different kinds. Others are required in the care of cattle, and for the dairy (q.v.). The principal agricultural implements are noticed in separate articles, and some in connection with particular kinds of cultivated plants.

IMPLU'VIUM, a tank or cistern in the center of the hall or atrium (q.v.) of a Roman house. In the examples which remain at Pompeii the impluvium is generally formed of marble. It is placed immediately under the unroofed part of the atrium, and is intended to receive the rain which runs down from the roof through the opening. The impluvium was frequently adorned with fountains, and formed a very peculiar and interesting feature in the dwellings of the Romans.

IMPONDERABLE SUBSTANCES, an epithet applied to light, heat, electricity, and magnetism, at a time when they were universally considered as matter, in contradistinction to those substances which possessed sensible weight. See HEAT.

IMPOON, *Antilope* or *Cephalopus mergens,* a small species of antelope, very plentiful in South Africa, in wooded districts. It is about 21 in. high at the shoulder, of a brownish-yellow color, with white belly. The horns are short and conical, set far back, and inclined backwards. It lives solitary or in pairs. From its habit of plunging amongst bushes when pursued, standing on its hind legs at intervals to observe its pursuers, and disappearing again, the impoon is called *duyker-bok* (diver-buck) by the Dutch colonists of South Africa, among whom its flesh is in great esteem.

IMPORTS AND EXPORTS. See BALANCE OF TRADE.

IMPORTS AND EXPORTS (*ante*), or Foreign Trade of the United States. In 1840, when ocean steam navigation began to be successful, the entire importations of merchandise into the United States was valued at only $86,250,335. The largest value of merchandise in any one year's importation was in 1873, the total being $642,136,210. The offset of exports for the years named was $111,660,561 in 1840, and $505,033,439 in 1873. From 1863 to 1873 the value of imports of merchandise largely exceeded the values of exports, the excess of imports ranging from $39,371,368 in 1863 to $182,417,491 in 1873. During the years ending June 30, 1876, '77, '78, and '79, however, the value of exports of domestic merchandise from the United States has greatly exceeded the value of imports, the excess of exports increasing rapidly from year to year. The countries from which imports come are, in the order of value for 1879: Great Britain, $108,538,812; Cuba, $63,649,656; France, $50,684,601; Brazil, $39,375,441; Germany, $35,519,818; British America, $26,133,554; China, $18,084,694; British East Indies, $12,225,770; Japan, $9,845,562; Italy, $7,884,327; Colombia, $6,330,946; Spanish possessions, $5,523,067; Mexico, $5,493,221; Dutch East Indies, $5,435,331; Venezuela, $4,855,034; Porto Rico, $4,384,954; Belgium, $4,209,232; British West Indies and Honduras, $3,719,085; Netherlands, $3,680,932; Argentine Republic, $3,518,105; Spain, $3,334,241; Hawaiian islands, $3,257,938; Hayti, $2,790,476; French West Indies and Guiana, $2,634,090; Central America, $2,251,589; Peru, $1,857,859; Uruguay, $1,780,140; all other countries, $8,770,303; total imports in 1879, $445,777,775. The principal articles of importation, and their value in specie, for the years ending June 30, 1878 and 1879, are given in the annexed table:

Commodities Imported.	1878.	1879.
Sugar	$71,924,267	$70,642,869
Molasses, melada, and cane syrup	7,902,181	8,645,197
Coffee	51,917,609	47,256,819
Silk, raw	5,103,084	8,371,025
" manufactures of	19,837,972	24,013,398
Wool, raw	8,363,015	5,034,555
" manufactures of	25,230,154	24,353,821
Chemicals, drugs, dyes, and medicines	24,738,469	27,038,808
Cotton, raw	469,882	499,931
" manufactures of	19,081,037	19,928,310
Hides and skins, except furs	17,223,363	15,959,017
Flax, raw	1,177,229	969,451
" manufactures of	14,413,600	14,693,842
Tea	15,660,168	14,577,618
Tin, and manufactures of	12,171,030	12,513,864
Breadstuffs and farinaceous food	8,800,499	10,614,173
Fruit and nuts, of all kinds	9,738,546	10,316,579
Iron and steel, and manufactures of	9,057,622	9,447,148
Leather, and manufactures of	7,469,359	7,556,854
Wood, and manufactures of	5,736,756	6,257,746
India-rubber and gutta-percha, and manufactures of	4,953,666	6,242,225
Wines, spirits, and cordials	5,517,427	6,037,033
Tobacco, and manufactures of	6,439,868	5,888,876
Jute, grasses, and manufactures of	4,104,588	5,557,897
Provisions, including eggs and fish	4,776,747	4,575,152
Furs, dressed and undressed	3,944,270	4,516,290
Fancy goods	4,200,737	4,119,217
Earthen, stone, and China ware	4,051,786	4,052,787
Precious stones	3,039,102	3,842,007
Glass and glass-ware	3,345,149	3,222,479
Buttons and button materials	3,362,085	3,197,070
Paper rags and material	3,993,669	3,196,243
Animals, living	2,664,676	2,794,129
Straw and palm leaf, manufactures of	2,296,266	2,508,679
Seeds	2,522,202	2,213,857
Books, engravings, and other publications	1,870,580	2,057,125
Hemp, raw and manufactured	2,443,953	1,936,069
Spices	1,936,217	1,824,171
Salt	1,632,825	1,776,741
Coal, bituminous	1,936,187	1,724,466
Metals, and manufactures of, not specified	2,068,570	1,582,884
Dyewoods in sticks	1,396,485	1,406,179
Paintings, photographs, and statuary	968,517	1,269,039
Paper, and manufactures of	1,466,625	1,186,382
Clothing, except of silk or hosiery	1,275,419	1,171,296
Hair of all kinds, and manufactures of	727,365	942,931
Watches and watch materials	812,582	920,599
Paints of all kinds	848,113	759,580
Marble and stone, manufactures of	746,956	689,288
Beer, ale, and porter	592,707	628,806
Musical instruments	561,867	627,722
All other merchandise	18,565,173	22,376,149
Total imports of merchandise	$437,051,532	$445,777,775
Total imports of coin and bullion	29,881,314	30,296,000

For the fiscal year ending June 30, 1880, the total imports of merchandise were $667,954,746. Total imports of coin and bullion, $93,034,310.

In the following table is given the value of the principal commodities of foreign production in which there has been a considerable decrease of importation since 1873, the year of the highest total importation:

Commodities.	1873.	1874.	1875.	1876.	1877.	1878.	1879.
	$	$	$	$	$	$	$
Clothing, including hosiery, etc. of cotton and wool	8,496,993	7,069,996	7,370,626	7,004,162	5,574,412	6,540,587	6,560,456

Exports of merchandise from the United States have increased rapidly in value in recent years. In 1845 the exports were a little less than $100,000,000 in value; in 1897 the value was $710,439,441. In 1845 the imports nearly equaled the exports; in 1879 the imports were only about 63 per cent of the exports. During 1879 the exports of domestic produce of the United States to Great Britain and Ireland amounted in value to $346,485,881, being 50 per cent of the total export of domestic merchandise for the year. There was a falling off in value of $37,121,030 from the preceding year, though the quantities of the several articles were about the same, the difference being caused by a decline in prices for cotton, wheat, corn, and some other articles. In the same period the value of exports to France rose from $54,289,918 to $88,194,041, the increase being chiefly in wheat. The principal countries to which the agricultural and other products of the United States are sent stood, in the order of value of exports in 1879, as follows: Great Britain and Ireland, $346,485,881; France, $88,194,041; Germany, $56,164,394; British America, $28,281,569; Belgium, $27,470,003; Russia, $15,959,701; Netherlands, $13,802,840; Spain, $12,438,903; Cuba, $12,201,691; Italy, $8,657,403; Brazil, $8,106,928; Australia, $7,042,875; British West Indies and Honduras, $6,779,153; China, $5,930,594; Mexico, $5,400,380; Colombia, $5,199,648; Portugal, $4,897,290; Turkey, $3,989,230; Hayti, $3,148,757; Japan, $2,674,601; Austria, $2,640,648; Hawaiian islands, $2,288,178; Denmark, $2,284,784; British Africa, $2,168,076; Sweden and Norway, $2,138,461; Argentine republic, $2,033,401; Venezuela, $1,926,923; Porto Rico, $1,771,483; British Guiana, $1,719,827; French West Indies and Guiana, $1,535,768; Dutch East Indies, $1,447,510; Gibraltar, $1,297,820; Peru, $1,293,991; Chili, $1,253,555; British East Indies, $1,142,196; Central America, $1,110,603; all other countries, $8,538,276; total exports of merchandise from the United States in 1879, $699,538,742.

In the following table is a comparison of the quantities of leading articles of export for three years, with the increase in 1879 over 1876:

Commodities.	Year ending June 30—			Exports of 1879 over 1876.	Per cent Increase.
	1873.	1876.	1879.

This immense commerce is done mainly by foreign vessels. In 1856 the percentage carried in American vessels was 72.2; in 1879 it was only 23. There has been a gradual but regular decrease of ocean trade in American vessels since 1868.

IMPOST, the point where an arch rests on a wall or column. It is usually marked by horizontal moldings, but sometimes these are absent, especially in Gothic architecture, where different forms of impost are used. These have been classed by prof. Willis as—1st, "the *continuous* impost," where the arch moldings are carried down the pier; 2d, "the *discontinuous* impost," where the arch moldings abut and are stopped on the pier; 3d, "the *shafted* impost," where the arch moldings spring from a capital, and are different from those of the pier—the form used in the best Gothic; 4th, "the *banded* impost," where the pier and arch have the same moldings; but the impost is marked by a band of horizontal moldings, as is frequently the case in Italian-Gothic buildings. These simple forms of impost are sometimes used together, so as to produce more complex combinations.

IMPOSTORS, THE THREE, the name of a work supposed to have been written against the Jewish, Christian, and Mohammedan religions, and often mentioned since the 19th century. Its title is *De tribus Impostoribus*. Its genuineness is doubtful.

IMPOTENCY, in law, is a good ground for either of two married parties annulling the marriage, if the impotency existed at the time the contract was entered into. The defect must be proved. The law is uniform in the United Kingdom.

IMPOUNDING A DOCUMENT occurs where a document is produced in course of a trial or hearing before a court or judge, who, instead of giving it up to the owner, retains it, in order to enable a prosecution to be brought if necessary.

IMPOUNDING CATTLE is, in English law, the remedy given to all occupiers of land against the cattle of strangers which stray on such land. It amounts, in fact, to taking and keeping the cattle as a security for the damage which has been done. The occupier is then said to distrain the cattle *damage feasant*. This he does by seizing and driving them to the nearest pound, if there is one within three miles—i. e., an inclosed place kept for the purpose—or he may put them in premises of his own. In either case, he is bound to feed and water the cattle at the expense of the owner of such stray cattle, who can only recover them back by paying these expenses and the damage done, or on giving security, and bringing an action of replevin (q.v.) to try the right. The cattle cannot be distrained unless they are at the time actually trespassing upon the land. In Scotland, a similar right exists, called the *pounding* of stray cattle.

IMPRESSMENT was once the mode formerly resorted to of manning the British navy. The practice had not only the sanction of custom, but the force of law, for many acts of parliament, from the reign of Philip and Mary to that of George III., had been passed to regulate the system of impressment. Impressment consisted in seizing by force, for service in the royal navy, seamen, river-watermen, and at times landsmen, when state emergencies rendered them necessary. An armed party of reliable men, commanded by officers, usually proceeded to such houses in the seaport towns as were supposed to be the resort of the seafaring population, laid violent hands on all eligible men, and conveyed them forcibly to the ships of war in the harbor. As it was not in the nature of sailors to yield without a struggle, many terrible fights took place between the press-gangs and their intended victims—combats in which lives were often lost. In point of justice there is little, if anything to be said for impressment, which had not even the merit of an impartial selection from the whole available population.

In recent times, when volunteers fail, a system of bounties (q.v.) has been resorted to; and it is not very probable that recourse will be again had to impressment. At the same time, the laws sanctioning it slumber, without being repealed.

Under the laws all eligible men of seafaring habits are liable between the ages of 18 and 55; but exemptions are made in favor of apprentices who have not been two years apprenticed, fishermen at sea, a proportion of able seamen in each collier, harpooners in whalers, and a few others. A press-gang could board a merchant-vessel or a privateer of its own nation in any part of the world, and carry off as many of the best men as could be removed without actually endangering the vessel. The exercise of this power made a privateer dread a friendly man-of-war more than an enemy, and often led to as exciting a chase as when enemies were in pursuit of each other; for the privateer's men were the best sailors for their purpose the naval officers could lay hold on.

IMPRISONMENT. The power of imprisonment for non-payment of debt, as well as by way of punishment for crime, has always been held to be inherent in courts of justice. In criminal proceedings also, a person may, by a warrant of a justice of peace, be imprisoned before trial, provided the justice considers it is not a proper case for allowing bail; and as a general rule, though in minor offenses an accused person may insist on being discharged on tendering sufficient bail, yet in more serious crimes it is always in the discretion of the justice to accept or refuse the bail tendered, and on his refusal, application may be made to judges of the common law courts to accept bail. As regards imprisonment for debt, it is now competent only in cases where there is fraud in contracting or contempt in not paying it. In one case, however, and one only, a person

may be imprisoned before judgment has been obtained—viz., where he is about to leave the kingdom. In such a case the creditor requires to make an affidavit of the debt or cause of action before a judge, and may obtain a *capias* to arrest the defendant, who will not be released, except on bail, until judgment is obtained. With regard to debts under £20, which are generally sued for in England in the county court, though the defendant cannot be imprisoned on a judgment for less than that amount, yet if he willfully disobey the judgment of the court, which ordered him to pay by installments or on a time certain, and if the debt was originally contracted by means of fraud, the judge can commit him for contempt, and thus imprison him on another ground. In cases of insolvency it is no longer an act of bankruptcy to suffer imprisonment for debt, but absenting one's self from business, leaving England, making a fraudulent assignment, etc., is an act of bankruptcy, and he may be adjudicated a bankrupt and his estate distributed in the usual way by the court of bankruptcy. But in general, if a person wishes to be made a bankrupt, he can become so without the necessity of being imprisoned. It was also a doctrine of the law of England that if a debtor was once imprisoned for debt it operated as complete satisfaction, and his land or goods could not then be taken. But the debtor could get out of prison through the bankruptcy court, which required him to give up everything to the creditors.

In Scotland imprisonment for debt has not been abolished as yet; and it is competent to imprison a debtor if the debt exceed £8 6s. 8d. An absconding debtor may also be arrested if *in meditatione fugæ*—i. e., about to leave the country, in which case bail or caution is required. In Scotland imprisonment for debt is not considered satisfaction of the debt, and the creditor may at the same time poind his goods and adjudge his land, and take other concurrent remedies.

IMPRISONMENT (*ante*) is the restraint of a person's liberty for any cause whatever, whether by authority of the government or in defiance thereof. In the latter case it is "false imprisonment." It does not necessarily imply a prison with bolts and bars, but may be exercised by an array of force, lawfully or unlawfully, in the open street. A man becomes a prisoner wherever he may be, by the mere word or touch of a duly authorized officer directed to that end. Usually, however, imprisonment is understood to imply an actual confinement in some jail or prison employed for the purpose according to the provisions of law. The power to imprison is, in many cases, inherent in courts or magistrates, and in others conferred upon them by statute, and it may be employed in civil as well as criminal proceedings. Imprisonment for debt, once universal in this country, under the operation of the English common law, is now generally abolished by statute, except in cases where the action of the debtor is tainted by fraud, or he is reasonably suspected of an intention to avoid his debt by concealing his property, or removing that and himself from the state. Witnesses whose testimony is necessary for the conviction of a criminal, often are imprisoned to prevent their escape from the jurisdiction of the court. Persons accused of crime are either confined till the day of trial, or released on bail, according to the gravity of the offense. Courts have the power to imprison for contempt of their authority, and persons found guilty of crime are imprisoned for periods definitely fixed by statute or by the judgment of the court. The confinement of lunatics in asylums appointed for the purpose is not here considered, as such asylums are not usually regarded as prisons. A person who wrongfully or illegally deprives another of liberty may be sued in a civil action for false imprisonment by the person aggrieved, or prosecuted as for a criminal offense. A prisoner desiring release is entitled to a writ of *habeas corpus* to obtain the judgment of a competent court as to the legality or illegality of his imprisonment.

IMPROBA'TION, a Scottish law-term, meaning the disproving or setting aside a deed on the ground of falsehood or forgery.

IMPROMPTU, in music, a short extemporaneous composition. See also FANTASIA.

IMPROPRIA'TION, the transfer to a layman of the revenues of a benefice to which the cure of souls is annexed, with an obligation to provide for the performance of the spiritual duties attached to the benefice. The practice of *impropriation* differs from the somewhat similar but more ancient usage of *appropriation*, inasmuch as the latter supposes the revenues of the appropriated benefice to be transferred to ecclesiastical or quasi ecclesiastical persons or bodies, as to a certain dignitary in a convent, a college, a hospital; while impropriation implies that the temporalities of the benefice are enjoyed by a layman; the name, according to Spelman, being given in consequence of their thus being *improperly* applied, or diverted from their legitimate use. The practice of impropriation, and still more that of appropriation, as in the case of monasteries, etc., and other religious houses, prevailed extensively in England before the reformation; and on the suppression of the monasteries, all such rights were (by 27 Henry VIII. c. 28, and 31 Henry VIII. c. 13) vested in the crown, and were by the crown freely transferred to laymen, to whose heirs have thus descended not only the right to tithes, but also in many cases the entire property of rectories. The spiritual duties of such rectories are discharged by a clergyman, who is called a vicar, and who receives a certain portion of the emoluments of the living, generally consisting of a part of the glebe land of the parsonage, together with what are called the "small tithes" of the parish.

IMPROVING LEASE, a lease, in Scotland, by which the tenant undertakes to keep the premises in repair; called a repairing lease in England.

IMPROVISATO'RI, an Italian term, designating poets who utter verses without previous preparation on a given theme, and who sometimes sing and accompany their voice with a musical instrument. The talent of improvisation is found in races in which the imagination is more than usually lively, as in the Arabs, and in many tribes of negroes. Amongst the ancients, Greece was the land of improvisation. In modern Europe, it has been almost entirely confined to Italy, where Petrarch, in the 12th c., introduced the practice of singing improvised verses to the lute; and down to the present day, the performances of improvisatori constitute one of the favorite entertainments of the Italians. Females (*improvisatrices*) have frequently exhibited this talent in a high degree. Improvisation is by no means limited to brief poems of a few verses and of very simple structure, but is often carried on with great art, and in the form and to the length of a tragedy or almost of an epic poem. But when the productions of the most admired improvisatori have been given to the world through the press, they have never been found to rise above mere mediocrity. It is worthy of notice that the greater number of the celebrated improvisatori of Italy have been born in Tuscany or the Venetian territories. Siena and Verona have been especially productive of them. Some of the principal are Serafino d'Aquila (died 1500), Metastasio (q.v.), who soon abandoned the art, Zucco (died 1764), Serio and Rossi (beheaded at Naples, 1799), Gianni (pensioned by Bonaparte), and Tommaso Sgricci (died 1836). The best-known *improvisatrices* are Magdalena Moralli Fernandez (died 1800), Teresa Bandettini (born 1756), Rosa Taddei (born 1801), Signora Mazzei (probably the first in point of talent), and more lately Giovannina Milli.

IMPULSIVE MADNESS. The approaches of mental disease are generally slow and perceptible; but instances occur where, without announcement, without any preliminary stage of disease or disturbance, an individual, apparently hitherto of sound mind, is suddenly seized with mania, presents symptoms of incontrollable violence, perpetrates acts of atrocity or absurdity, altogether inconsistent with his previous disposition and deportment; and then, nearly as quickly, subsides into his ordinary state and habits, retaining no, or a very imperfect, recollection of the events which occurred during the paroxysm. It is not, however, in the suddenness or shortness of the paroxysm that the essential characteristic consists. During the continuance of such an affection, three mental conditions are distinctly traced: 1. The sudden birth and irresistible dominion of a propensity; 2. The abolition or impairment of the apprehension of the real and ordinary relations of the individual; and 3. The suspension of the powers by which such propulsions are prevented from arising, or ruled and regulated when they do arise. Alienation of this kind has been chiefly recognized when the instincts are involved; and the most striking illustrations are derived from cases of homicidal or sanguinary tendency, simply because the results may convulse society, or come under the notice of courts of law. But many examples exist of brief periods of aberration which could not be instigated by passion, and involved nothing criminal. A lady is mentioned who never entered church but she was impelled to shriek, or saw plate-glass but she was impelled to break it; and the incongruous laughter, the grotesque gesticulations, and the involuntary and repulsive associations to which good and great men have been subject, must all be placed under this category.

Marc, *De la Folie considérée dans ses Rapports avec les Questions Medico Judiciaires*, t. i. p. 219, and t. ii. p. 473.

IMPUTA'TION is one of the most common technical expressions in Christian theology. It is meant to denote the transference of guilt or of merit of punishment or reward. The doctrine of the imputation of sin, for example, is the doctrine which inculcates that all mankind are sharers in the fact and consequences of Adam's fall from innocence; and the correlative doctrine of the imputation of Christ's righteousness is that which inculcates that the merit or righteousness of Christ is transferred to those who believe in him, or, in other words, that they become sharers in his merit or righteousness. This idea of transference of intercommunication of good and evil, is a pervading one in Christian theology, and answers to undoubted realities of the spiritual life; but the idea is also apt to become degraded and materialized, and has become so in some of its common representations in popular theology. The doctrine of the imputation of Adam's sin, for example, expresses to some minds not only the idea of the participation of the human race in the consequences of Adam's transgression, so that, because he sinned and fell from innocence, they, the inheritors of his corrupt nature, also sin, and are involved in the miseries of a sinful state; but, moreover, the idea, that the sin of Adam in its direct guilt and wickedness is transferred to his posterity. They reason after this manner: it is undeniable that man suffers on account of original sin; but suffering and sin are inseparably connected. If man suffers on account of original sin, therefore, it is only because he is guilty of it. The sin of Adam in eating the forbidden fruit is equally the sin of his posterity. According to this mode of reasoning, there is a formal imputation of the sin of Adam to all his descendants. God is supposed, as it were, to charge the one to the account of the other, and by a direct and arbitrary act to hold mankind guilty because Adam fell. To give a logical justification to this view, it is assumed that God entered into a covenant with Adam (see COVENANT), by which the latter was

regarded as a representative of the whole human race; so that when he fell, all mankind sinned and fell with him. In the same manner, the merit or righteousness of Christ is supposed to be *imputed* to believers by a direct and formal transference of the one to the account of the other. In both cases it is the idea of formal and arbitrary exchange that is prominent; and according to some theologians, this idea alone answers to *imputation* of sin or of righteousness. To *impute* sin, is to deal with a *man as a sinner*, not on account of his own act, or at least not primarily on this account, but on account of the act of another; and to *impute* righteousness, is to deal with man as righteous, not because *he is so*, but on account of the righteousness of Christ *reckoned as his*, and received by faith alone. The act of another stands in both cases for our own act, and we are adjudged—in the one case condemned, in the other acquitted—not for what we ourselves have done, but for what another has done for us.

This is a fair illustration of the tyranny which technical phrases are apt to exercise in theology as in other things. When men coin an imperfect phrase to express a spiritual reality, the reality is apt to be forgotten in the phase, and men play with the latter as a logical counter, having a force and meaning of its own. *Imputation of sin* and *imputation of righteousness* have in this way come to represent legal or pseudo-legal processes in theology, through the working out of the mere legal analogies suggested by the word. But the real spiritual reality which lies behind the phrases in both cases is simple enough. *Imputation of sin* is, and can be nothing else than the expression of the spiritual unity of Adam and his race. Adam "being the root of all mankind," the stock which has grown from this root must share in its degeneracy. The law of spiritual life, of historical continuity, implies this, and it requires no arbitrary or legal process, therefore, to account for the sinfulness of mankind as derived from a sinful source. We are sinners because Adam fell. The fountain having become polluted, the stream is polluted. We are involved in his guilt, and could not help being so, by the conditions of our historical existence; but, nevertheless, his sin is not our sin, and cannot in the strict sense be imputed to us, for sin is essentially voluntary in every case—an act of self-will, and not a mere quality of nature; and my sin, therefore, cannot be another's, nor another's mine. In the same manner, the highest meaning of the imputation of the righteousness of Christ lies in the spiritual unity of the believer with Christ, so that he is one with Christ, and Christ one with him, and in a true sense he becomes a partaker of the divine nature. The notion of legal transference is an after-thought—the invention of polemical logic—and the fact itself is deeper and truer than the phrase that covers it. *The race one with Adam*, the *believer one with Christ*, are the ideas that are really true in the phrases *imputation of sin* and *imputation of righteousness*. The logic of theology has evolved many more applications of the phrases, but these applications are rather the refinements of theological pedantry than the expression of true spiritual relations.

INACHUS, a name in Grecian mythology given to a river in Argos, and also to the god of the river. When Neptune and Juno disputed about the possession of Argos, and Inachus decided for Juno, Neptune is said to have dried up the river. Inachus is described also as the first king of Argos and leader of the Argives from the mountains to the plains, from whom Argos is called Inachian.

INA'GUA, GREAT and LITTLE, are the two most southerly islands of the Bahama group, the former of which, measuring 50 m. by 25, is remarkable for having its longer dimension placed almost at right angles to those of the rest of the cluster. The Little Inagua lies about 12 m. n., and measures 8 m. by 6. The pop. of both islands together is about 1000, of whom only a small proportion are white.

INAJA' PALM, *Maximiliana regia*, a South American palm, common in the countries near the Amazon; having a lofty, massive stem; very long, drooping, pinnate leaves, with leaflets in groups of three, four, or five at intervals along the midrib, from which they stand out in different directions; numerous spadices; large woody spathes; and densely clustered elongate fruit, with a hard stony seed, a layer of soft pulp, and a tough skin. The leaves are sometimes more than 50 ft. long. The great woody spathes are used by hunters to cook meat in, and with water in them, they stand the fire well enough for the purpose. They are also used as baskets and as cradles by the Indians. The fruit is eaten by the Indians, and is particularly attractive to monkeys and some kinds of birds.

INANI'TION. See STARVATION.

INARCH'ING, or GRAFTING BY APPROACH, a mode of grafting by which branches are united together before any of them is separated from its original stem. Branches growing across one another sometimes unite in this way of themselves, and it is supposed—not improbably—that an observation of this circumstance first led to the invention of grafting. Inarching is practiced in cases in which the ordinary modes of grafting are not found readily to succeed, as with camellias. The stocks to be grafted upon are planted, or placed in pots, around the plant from which the grafts are to be taken. Four or five months are generally sufficient to complete the union, but sometimes even two years are necessary. When the union is complete the scion is separated by a sloping cut from its parent plant. Care must always be taken that the parts to be joined together be cut so as to fit one another pretty exactly, and they are then firmly tied together, and so

covered that neither air nor water may penetrate. It is desirable that they be branches of nearly the same thickness. They should be cut almost down to the pith, but the pith must not be injured. Inarching is performed in spring, after the sap has begun to circulate. There are several ways of inarching. For example, two branches of a tree may be bent so as to meet and strike upon a wound in the main stem, by which a gap will be filled up; one growing tree either from the ground or a pot, may be led to unite with another; or several suckers may be led from the ground archwise to strike upon a point in the stem, thus bringing fresh aid to the productive part of the tree. By means such as these, quickset-hedges are sometimes thickened like a net-work, so as greatly to improve their appearance and protective qualities.

IN ARTICULO MORTIS, a phrase used in Scotland to denote a deed executed on death-bed. As a general rule, such a deed, in Scotland, operating like a will, may be set aside by the heir-at-law. But a will in England having the same effect cannot be set aside on that ground.

INCANTA'TION, like *enchant*, is derived from a Latin root meaning simply "to sing," as *charm* is only a disguised form of *carmen*, a song. It is the term in use to denote one of the most powerful and awe-inspiring modes of magic (q.v.), viz., that resting on a belief in the mysterious power of words solemnly conceived and passionately uttered.

There is in the human voice, especially in its more lofty tones, an actual power of a very wonderful kind to stir men's hearts. When to this we add that poetic utterance is a special and exceptional gift; that the language of primitive nations is crude and unmanageable, the words being as difficult to weld together as pieces of cast-iron; that it is only when the poet's mind has risen to unusual heat that he can fuse them into those rhythmical sequences that please the ear and hang together in the memory; that, in short, his art is a mystery to himself—an inspiration; we need not wonder at the feeling with which everything in the form of verse or meter was viewed.

The singing or saying of such compositions, which could thus stir the blood of the hearers, they knew not how, what other effects might it not produce? Accordingly, there is no end to the power ascribed to incantations, especially when accompanied, as they generally were, with the concocting of drugs and other magical rites. They could heal or kill. If they could not raise from the dead, they could make the dead speak, or "call up spirits from the vasty deep," in order to unveil the future. They could extinguish fire; darken the sun or moon; make fetters burst, a door or a mountain fly open; blunt a sword; make a limb powerless; destroy a crop, or charm it away into another's barn.

The prayers of heathens, whether for blessings or for curses, partake largely of the nature of magical incantations. They are not supposed to act as petitions addressed to a free agent, but by an inherent force which even the gods cannot resist. This notion is very prominent in Hinduism and Buddhism; but it more or less disguisedly pervades all superstitious worship. "They think they shall be heard for their much speaking."

For almost every occasion or operation of life, there were appropriate formulas to be repeated in order to secure success; and many of these, with that reverence for antiquity and conservative tendency which always characterize superstition, continue to live in popular memory, although often the words are so old as to be unintelligible. The Romans, in the days of Cato, used incantations, for curing dislocations, full of words the meaning of which had been lost. A form of words used to this day in Shetland for healing a sprain can be traced back to the 10th century. In its earliest form, as found in an old German manuscript, it narrates how Woden and Baldur riding out to hunt, Baldur's horse dislocated its foot, and how Woden, using charmed words, set bone to bone, etc., and so healed the foot. The repetition of this rhymed narration acted as a charm to heal other lamed horses. The modern version of this tradition, as current in Norway, makes the accident happen to the horse of *Jesus*, and Jesus himself perform the cure. In Shetland, also, it is the Lord, meaning Jesus, that is substituted for Woden; and the formula is applied to the healing of persons' limbs as well as those of horses. The operation is thus described in R. Chambers's *Popular Rhymes of Scotland:* When a person has received a sprain, it is customary to apply to an individual practiced in casting the "wresting-thread." This is a thread spun from black wool, on which are cast nine knots, and tied round a sprained leg or arm. During the time the operator is putting the thread round the affected limb, he says, but in such a tone of voice as not to be heard by the bystanders, nor even by the person operated upon:

Our Lord rade,
His foal's foot slade;
Down he lighted,
His foal's foot righted.
Bone to bone,
Sinew to sinew,
Blood to blood,
Flesh to flesh.
Heal, in name of the Father, Son, and Holy Ghost.

INCARNA'TION (Lat. *in*, and *caro, carnis*, flesh), a term much used in theology concerning the union of the divine nature of the Son of God with human nature in the

person of Christ. We read in John, i. 14, that "the Word was made flesh;" but this is understood not as signifying a change of nature, but an assumption of human nature into personal union with the divine nature. In accordance with Luke, i. 35, and other texts of Scripture, the formation of the human nature of Christ is ascribed to the Holy Ghost. The reality of the human nature of Christ was much disputed in the first ages of Christianity, but in our times the chief dispute as to the person of Christ relates to his divine nature. Whilst the doctrine of the incarnation is generally asserted by all who profess Christianity, except Unitarians (q.v.), no explanation of it is attempted or deemed possible. It is regarded, however, as a doctrine fraught with most important consequences, affecting the whole system of Christianity. In the doctrine of the incarnation, it is maintained that in union with the divine nature of the Son of God, there was, and is, in the person of Christ, not only a true human body, but a human "reasonable" soul.

INCARNATION, THE (*ante*). The coming of the Son of God in human flesh is the great fact which gives unity to the Scriptures and reveals God to men. Before it was accomplished it was prefigured in a series of preliminary manifestations of the Deity in human form, to whom the Scriptures ascribe the names Angel Jehovah, Jehovah, and God. See JEHOVAH. The incarnation of God in Jesus Christ, fully denied by some, indeterminately held by many more, but by the great majority of thinkers in Christendom accepted in various forms of philosophic statement, may be briefly outlined from the Scriptures on whose testimony it rests. A permanent and perfect union of the Divine being and the human nature has been constituted in human history in the person of Jesus the Christ, and this not as creating a unity previously non-existent, but as restoring and historically developing a perfectly *natural* union. 1. That this would be done was foretold by prophecy. (1) It promised that the Messiah of God would be a man. The first announcement of a deliverer was made after the fall of man, in the Lord's declaration to Satan under the guise of the serpent: "I will put enmity between thy seed and the seed of the woman; he shall bruise thy head and thou shalt bruise his heel." The promise to Abraham was that in him and his seed (whence, according to the flesh, Christ came) all the families of the earth should be blessed. Jacob's prophecy implied that the Shiloh, the giver of peace, would be a descendant of Judah. The Lord's covenant with David was that, in the distant future, his exalted son should sit on his throne. David describes the mortal suffering of a man whose soul should not be given up to the dead, nor his body to the corruption of the grave. Isaiah foretold that a child would be born who should exercise government on the throne of David; that a man would be as a covert from the tempest; and that the anointed servant of the Lord would be a man of sorrows, rejected of men, bearing the sins of many, and that he would die and be buried. Jeremiah prophesied that there would be raised up to David a righteous branch and prosperous king. Daniel was instructed by the angel that, at the time appointed, the Messiah would be cut off, but not for himself. Zechariah proclaimed the man whose name is "the Branch;" who would be a king and priest on his throne; would be lowly, riding on the foal of an ass; and be smitten as the shepherd of the flock. Micah announced that the promised ruler of Israel would be born at Bethlehem. (2) Prophecy declared that the Messiah would be a divinely human personality. David called him who in the future would sit on his throne, his lord; saying, Jehovah said to my lord, sit thou on my right hand. Therefore, since in his human nature he was to be David's son, he must possess also the divine personality in order to be David's lord. Isaiah foretold that the name of the child to be born and to rule over the kingdom of David would be Wonderful, Counselor, the mighty God, the father of eternity—that is, according to the Hebrew idiom, the Eternal. Jeremiah prophesied that the name of the future righteous son of David would be Jehovah our righteousness. Zechariah said that the man who would be smitten as the shepherd is the "fellow" of Jehovah; and that he whose feet would stand on the Mount of Olives is Jehovah. Micah declared that the going forth to rule of him who would be born in Bethlehem was only one of those goings forth which have been from of old, even from everlasting. Malachi gives the closing assurance that the angel of the covenant, the Messiah, who would suddenly come to his temple, is the Lord. 2. The New Testament declares that the union of the divine being and the human nature has been historically constituted in the person of Jesus Christ. (1) It speaks of him as a man of the house and lineage of David; narrating his birth, childhood, youth, manhood, words, works, sufferings, and death; recording more than 60 times his own application to himself of the title, the Son of Man; and saying that he ate, spake, heard, slept, walked, wept, and became weary; ascribing to him the emotions, affections, and sentiments of a true humanity. (2) It ascribes to him a personality properly divine: recording more than 100 times the application to him of the title Son of God in a sense in which it is not given to any other being; appropriating to him hundreds of times the title Lord, which corresponds to Jehovah in the Old Testament; affirming that he was "the Word" which was in the beginning with God, was God, and is the true God; assigning to him the attributes of God; prescribing for him the worship and honor due to God, and attributing to him the works of God. (3) Affirming his pre-existence in the bosom of the Father—and his even then continuing existence therein—together with his historical assumption of the

human nature, the New Testament teaches that he unites the true divine being and the true humanity in one person. It declares that the Son to whom it was said, "Thy throne, O God, is forever and ever," was brought into this world; that the Word who was with God and was God became flesh and dwelt among men, some of whom saw his glory, the glory as of the only-begotten of the Father; that he who was in the form of God took on himself the form of a servant, and was made in the likeness of men; that that which was from the beginning, the word of life, the eternal life which was with the Father, manifested in the world, was heard, seen, gazed on, and touched by men; that God was manifested in the flesh; and that he who is a descendant from the whole scriptural line of the fathers, is also over all, God blessed forever.

The view, not widely spread but ably advocated, that Christ was in no strict and proper sense the incarnation of God, does not base itself on the Scriptures, though seeking incidental confirmations in them. On the point under consideration, it stands in either a philosophical or a historical denial, usually in both; and this denial involves at least one of three modes of dealing with the Bible: (1) a refining of its language into a sense far from the ordinary use of words; (2) a doubt of the correctness of the scriptural documents as documents, in view of their liability to accidental changes in their transmission from antiquity; (3) a denial of the original authority of the Scriptures as a declaration of truth—this denial extending beyond the question of their infallibility, beyond that of their divine inspiration, to that of their truthfulness as mere human history or of their truthfulness as the testimony of men who claimed to be eye-witnesses of the facts which they record.

Philosophically, the incarnation of God touches the deepest problems; and historically its principle is traceable through many distortions in the great religions of the world.

INCAS. See PERU.

INCENDIARY LETTER, a letter threatening to burn the house or premises of a person, generally called a threatening letter. To send such a letter is felony, punishable by three years' penal servitude. The offense is punishable in Scotland according to the discretion of the court.

INCENDIARY SHELLS, another name for carcasses (q.v.).

INCENSE (Heb. *miktar*, *ketter*, and *kitturoth*), a perfume, the odor of which is evolved by burning, and the use of which, in public worship, prevailed in most of the ancient religions. The incense at present in use consists of some resinous base, such as gum olibanum, mingled with odoriferous gums, balsams, etc. There is no regular formula for it, almost every maker having his own peculiar recipe. The ingredients are usually olibanum, benzoin, styrax, and powdered cascarilla bark. These materials, well mingled, are so placed in the censer or thurible as to be sprinkled by falling on a hot plate, which immediately volatilizes them, and diffuses their odor through the edifice.

Among the Jews, the burning of incense was exclusively employed as an act of worship, and, indeed, would appear to have been in itself regarded in the light of a sacred offering. The same would also appear for the religion of Egypt; but the Persian sculptures exhibit the burning of incense as one of the marks of honor offered to royalty.

In the Catholic church, both of the west and of the east, incense is used in public worship, more particularly in connection with the eucharistic service, which is regarded as a sacrifice; but writers are not agreed as to the earliest date at which its use can be traced. St. Ambrose, in the western church, alludes to incense in terms which suppose the practice of burning it to be an established one; and in later writers, it is mentioned familiarly as a part of ordinary public worship. In the Roman Catholic church incense is used in the solemn (or high) mass, in the consecration of churches, in solemn consecrations of objects intended for use in public worship, and in the burial of the dead. There are also minor incensations of the celebrating bishop or priest and inferior ministers; of prelates, princes, and other dignitaries officially present at the public service, and a general incensation of the whole congregation.

In the reformed churches, the use of incense was abandoned at the same time with other practices which have been laid aside by them as without "warrant of Scripture."

INCENSED, or ANIMÉ, an epithet applied in heraldry to panthers or other wild beasts borne with flames issuing from their mouths and ears.

INCEST (Lat. *in*, not; *castus*, chaste) is the marrying of a person within the Levitical degrees. In the old ecclesiastical law (now obsolete), and in Scotland, it comprehends cohabitation irrespective of marriage. The law of England enforced these prohibitions by several statutes in the reign of Henry VIII., which are still in force. Recent cases have determined that a marriage between a widower and his deceased wife's sister comes within these rules, and is void, and it makes no difference that the marriage was celebrated in a foreign country, as, for example, Denmark, where these marriages are legal, provided the parties were domiciled in England, and went there merely to evade the English law. It has also been decided in England that the same rules which apply between legitimate relations apply between natural relations, though one is illegitimate—as, for example, between a man and the daughter of an illegitimate

sister of his deceased wife. Though incestuous marriages are utterly void in England, still it is not a criminal offense to marry incestuously, not even in those cases in which the connection is most abhorrent to the moral sense of mankind, and the remedy in the ecclesiastical courts may be considered obsolete. In Scotland incest, which is calculated on the same grounds, not only makes a marriage void, but the better opinion is that to marry incestuously, as well as to commit incest, is a capital offense. See MARRIAGE.

INCH, a Gaelic word, corresponding to Irish *innis*, and signifying island (q.v.); the same root appears in Lat. *ins*-ula. Inch and innis enter into many compounds, as Inchcolm (q.v.), Inniscattery, an island in the estuary of the Shannon.

INCHBALD, ELIZABETH SIMPSON, 1753–1821; b. England; was the daughter of a farmer, and distinguished herself as an actress, dramatic author, and novelist. After failing in her first attempts on the stage, she married Inchbald, the comedian, who trained her in the dramatic art, and with him she acted in several theaters in England, and in Edinburgh, with applause. After his death she wrote plays, and played at Covent Garden for nine years, and then devoted herself with success to literary pursuits. Her published works are dramas translated from German and French; *The British Theater*, 47 vols.; *The Modern Theater*, 10 vols.; a collection of *Farces*, 7 vols.; and a Romance in 4 vols. *A Simple Story*, translated into several European languages, and *Nature and Art*, have been very popular. Her *Memoirs*, a work of much interest, compiled from an autograph journal kept for 50 years, were published in 1833.

INCHCOLM (of old, "St. Colm's Inch," as in Shakespeare's *Macbeth*, act i. sc. 2; in Lat. *Aemonia*, and *Insula Sancti Columbæ*), an islet, beautifully placed in the firth of Forth, within sight of Edinburgh. It is separated from the n. of Fife shore by a channel less than a mile broad, called "Mortimer's Deep." The isle is somewhat more than half a mile in length, and less than a third of a mile broad where widest. It had a pop. in '71 of 6. It takes its name from St. Colm or Columba (q.v.) of Iona, who is said to have dwelt here while laboring for the conversion of the northern Picts in the 6th century. In the year 1123 king Alexander I. of Scotland, being shipwrecked upon it, found it inhabited by a solitary hermit, who lived on shell-fish and the milk of one cow, and served St. Columba in a little chapel or oratory. The king, in gratitude for his escape, founded on the island an abbey of Austin canons regular. Walter Bower, the enlarger and continuator of the *Scotichronicon* of John of Fordun (q.v.), was abbot of the monastery from 1418 till 1449. It was repeatedly sacked by the English during the 14th, 15th, and 16th centuries. The buildings, which have long been in ruins, show traces of Romanesque work (of about the middle of the 12th c.); but are chiefly first pointed (of the 13th and 14th centuries). The tower has some resemblance to the tower of Iona. The oldest edifice is a little vaulted oratory (20 ft. long by 7 broad), believed to represent the chapel in which king Alexander found the anchorite serving St. Columba in the 12th century. It is of the same type as the Irish oratory of Gailerus. It has been lately restored. There is also a chapter-house with a groined roof, and three elegant sedilia. The history of Inchcolm has been written with great detail by prof. sir James Y. Simpson, in the *Proceedings of the Antiquaries of Scotland*, vol. ii. pp. 489–528.

INCHKEITH, an island in the firth of Forth, nearly midway between Leith and Kinghorn. It is a mile in length, and not much more than a third of a mile broad where widest. Its pop. in '71 was 9. It is believed to be the site of the town or stronghold of Giudi, described by Bede (who wrote about 731 A.D.) as situated in the middle of the great arm of the sea which runs into Britain from the e. (that is, the firth of Forth). From the island fortress of Giudi, the inlet in which it stood was of old called "the sea of Giudin," and hence also, probably, Inchkeith took its name. The island is said to have been the site of a church or monastery, founded between 679 and 704 A.D. by St. Adamnan, the biographer of St. Columba, and his successor in the abbacy of Iona. Inchkeith was seized by the English in 1547, when they built a fort, which, in 1549, was taken by the French auxiliaries of Scotland, who gave the island the name of the "Isle of Horses." A light-house was built on the site of the fort in 1804. The island, which belongs to the duke of Buccleuch, is part of the parish of Kinghorn, in Fife.

INCIDENCE, ANGLE OF. See CATOPTRICS.

INCIDENT DILIGENCE. In Scotch law, letters of incident diligence are issued to compel the attendance of witnesses and havers at a trial. In England, a subpœna and a subpœna *duces tecum* are similar writs.

INCIPITUR, in English law, the formal commencement of a judgment in a common law court.

INCLEDON, BENJAMIN CHARLES, 1764–1826; b. England. Educated as a musician in the choir of Exeter cathedral, he excelled as a ballad-singer for 25 years. He visited the United States in 1817, but his voice had failed through age, and he was not greatly successful, though his singing in the old cathedral in New York was long remembered.

INCLINED PLANE, THE, is reckoned one of the mechanical powers (q.v.), because by rolling it up a plane, a man may raise a weight which he could not lift. The

principle is extensively made use of, chiefly in the raising of weights and in road-making. It is here unnecessary to go into a mathematical investigation of the theory of the inclined plane, as it may be seen in the common books on mechanics, but the result is as follows: The force required to lift a body (viz., its weight) bears to the force required to keep it from rolling down an inclined plane, the same proportion that the length of the inclined plane bears to its height; also the weight of the body bears to the weight which tends to bend or break the inclined plane, the same proportion that the length of the plane bears to its base. Let us suppose a plane, whose length is 13 ft.; base, 12 ft.; and height, 5 ft.; and let the weight be 780 lbs. Then the force which can sustain 780 lbs. on the inclined plane is five-thirteenths of 780, or 300 lbs. (i.e., a force which could just lift 300 lbs.); also the force which presses perpendicularly on the plane is twelve-thirteenths of 780, or 720 lbs. When the weight has not only to be sustained on the plane but drawn up it, the resistance of friction (q.v.) has to be added to the power necessary to sustain the weight. In common roads, engineers are agreed that the height of an incline should not exceed one-twentieth of the length, or, as they phrase it, the *gradient* should not be greater than one in twenty. It may here be mentioned that knives, chisels, axes, wedges, and screws are merely modifications of the inclined plane, but the last two being generally classed as distinct mechanical powers, will be treated each under its own head.

IN CŒNA DOMINI, a celebrated papal bull, so called from the ancient day of its annual publication, Holy Thursday. It is not, as other bulls, the work of a single pope, but with additions and modifications at various times, dates back from the middle ages; some writers tracing it to Martin V., others to Clement V., and some to Boniface VIII. Its present form, however, it received from the popes Julius II., Paul III., and finally Urban VIII., in 1627, from which year it continued for a century and a half to be published annually on Holy Thursday. The contents of this bull have been a fertile subject of controversy. It may be briefly described as a summary of ecclesiastical censures, especially of those with which grievous violation of the faith of the church, or of the rights of the church or of the Roman see, are visited; excommunication being denounced against heresy, schism, sacrilege, usurpation of the rights of the church or of the pope, forcible and unlawful seizure of church property, personal violence against ecclesiastics, unlawful interruption of the free intercourse of the faithful with Rome, etc. The bull, however, although mainly dealing with offenses against the church, also denounces under similar censures other crimes, as piracy, plunder of shipwrecked goods, forgery, etc. This bull, being regarded by most of the crowned heads of Europe as an infringement of their rights, encountered in the 17th c. the determined opposition of nearly all the courts, even the most Catholic; and at length, in 1770, Clement XIV. discontinued its publication, which has never since been renewed.

INCOMBUSTIBLE FABRICS have of late years become of great importance, owing to the terrible frequency of death from the ignition of clothing; the search, however, after some means of rendering garments incombustible has continued from a very early period (see Beckmann's *History of Inventions*). After many more or less successful attempts by Gay-Lussac and other chemists, Messrs. Versmann & Oppenheim communicated to the British association at Aberdeen, in 1859, the results of a series of experiments for rendering linen, calico, muslin, and all other vegetable fibers uninflammable.* They found that many salts possessed this power, but at the same time some of these injured the fabric, spoiled the color, or were so very expensive as to render their general use impossible. Two, however, viz., tungstate of soda and sulphate of ammonia, produced the best results without injuring the tissue or color of the fabric. The first of these acts physically by preventing contact with the air, and does not interfere with the processes of ironing and starching; it is therefore preferable for goods requiring washing. The best method of applying it is by mixing in the proportion of 4 oz. of tungstate of soda to 1 dram of phosphate of soda (to prevent the formation of a partially insoluble bitungstate), and dissolving the whole in an imperial pint of water. For fabrics which are worn without previous washing, sulphate of ammonia is preferable, and a solution containing 7 per cent of the crystalline salt is a perfect preservative. In printed muslins of a madder purple, however, a slight paleness of color is produced, but in no other case is the color affected, nor does it interfere with the ironing process. It is to be regretted that these simple and efficacious preservatives have not come into general use.—The incombustible fabrics of the ancients were formed of asbestos (q.v.).

INCOME-TAX, a tax imposed on all persons having incomes above a certain amount, whether from lands or labor. Various acts have passed from time to time to impose this tax—the first introduced by Pitt, and latterly revived in 1842 by sir Robert Peel, since which date it has been continued—the fairness and public policy of which have given rise to long and endless controversy. See TAXATION.

INCOME TAX (*ante*). An income tax has been very unpopular in both England and the United States. Even its advocates are in favor of leaving incomes below a certain amount untaxed altogether. In England incomes under £100 are exempt, and those

* Silks, worsteds, and animal fibers may be ignited and charred, but they do not burst into flame, because the gases they yield are not inflammable; vegetable fibers, on the other hand, largely evolve carbureted hydrogen.

between £100 and £150 pay a lower percentage. One-sixth of the revenue of Great Britain is said to be derived from this source. In the United States the government imposed an income tax from 1863 to 1872, exempting at first $600, and levying 5 per cent on all incomes above that to $5,000, 7 per cent on those from $5,000 to $10,000, and 10 per cent on all above $10,000. The tax afterwards was exempted on $1000 and later on $2000 The largest amount received from personal incomes was $61,000,000 in 1866 from nearly half a million persons assessed. The receipts in 1867 were $27,418,000; in 1868, $23,390,000; in 1869, $27,353,000; in 1870, $26,153,000. The income tax expired by limitation at the close of 1871.

INCOMMEN'SURABLE MAGNITUDES, or INCOMMENSURABLE QUANTITIES, are those which have no common measure, i.e., are not, both of them, multiples of the same unit, however small that unit be taken. Examples of incommensurable magnitudes are abundant in mathematical science. Thus, the side and diagonal of a square; the diameter and circumference, or diameter and area of a circle, etc.; 2 and $\sqrt{3}$; $\sqrt{5}$ and $\sqrt{7}$, etc. The term incommensurable magnitudes is used in arithmetic to denote two numbers which have no common measure greater than unity.

INCORPORA'TIONS. See CORPORATIONS.

INCORPO'REAL HEREDIT'AMENT. See HEREDITAMENT.

INCUBA'TION, THE PERIOD OF, or the duration of the time in which birds sit on their eggs before the young are hatched, varies in different species, but is nearly constant in each. In the humming-birds, the smallest animals of this class, it is only 12 days; in canaries, it is from 15 to 18 days; in the common fowl, it is 21 days; in the duck, it is from 28 to 30 days; in the guinea-fowl, it is 28 or 29 days; in the turkey, 30 days; and in the swan, from 40 to 45 days. A certain degree of heat (about 104°) is necessary for the development of the young bird; that of the sun is sufficient, during the day, to hatch the eggs of some birds (for example, the ostrich) inhabiting tropical countries, but in general the mother keeps up a suitable temperature by placing the eggs in a warm and carefully constructed nest (q.v.), and by covering them with her own body. In some cases, the male bird takes part in this duty; usually, however, his services are restricted to providing his mate with food.

Eggs may, however, be hatched without the aid of the parent bird. From time immemorial, the Egyptians have hatched eggs by artificial warmth in peculiar stoves called *mammals*. In 1777 Mr. Bonnemain devised an apparatus by which, for several years before the French revolution, he supplied the Parisian markets with excellent poultry, at a period of the year when the farmers had ceased to supply it. A description of this apparatus is given in Ure's *Dictionary of Arts*, etc., 7th ed. 1875, vol. ii.

The process of artificial incubation was publicly exhibited some years ago in London, by means of the *eccaleobion machine* (derived from *ekkaleo*, I call forth, and *bion*, life), which was invented by Mr. Bucknell, and is described in his *Treatise on Artificial Incubation*. This machine possessed a perfect control over temperature from 300° Fahrenheit to that of cold water for any length of time, and "by means of this absolute and complete command over the temperature, the impregnated egg of any bird, not stale, placed within its influence at the proper degree of warmth, is, at the expiration of its natural time, elicited into life, without the possibility of failure." That chickens were hatched in large numbers by this machine is undoubted, but for some reason—probably from the process not proving sufficiently economical for commercial purposes—the *eccaleobion* has not been lately heard of. In 1825 M. D'Arce obtained chickens and pigeons at Vichy by artificial incubation effected by the thermal waters there.

INCUMBENT, the rector, parson, or vicar holding an ecclesiastical benefice in England or Ireland. It is seldom used in Scotland except popularly in a similar sense.

INCUMBERED ESTATES COURTS are tribunals, established under recent statutes, for the purpose of disposing more readily than the ordinary judicial machinery will permit, of landed property subject to incumbrances, or legal claims at the instance of other persons than the proprietors. The want of such courts was first felt in Ireland. A quarter of a century ago the rents of many Irish estates did not suffice to pay the interest of the debts created over them, and the number of such incumbered properties was increased by the abolition of the corn-laws in 1846, which lessened the demand for those products of tillage which had rendered the cultivation of the soil possible by cottier tenants. It was believed that Ireland must become a grazing country; but that it could only do so in the hands of capitalist farmers, or landlords farming their own lands, and that a complete revolution in tenure was required to put them in possession of the soil. The sluggish and expensive procedure of the court of chancery made it impossible to effect this; and it became necessary to call into existence some more simple machinery by which property could be transferred from the old to a new class of proprietors. An auction-mart rather than a legal tribunal was wanted, under the control of officers able to scrutinize titles and adjust claims on landed property with care, yet without undue delay, and authorized to sell incumbered estates in the open market, to hand over a good and simple title to the purchasers, and to divide the sum realized among the proprietors, mortgagees, and others concerned, according to their interests. To accomplish this, an act (11 and 12 Vict. c. 48) was passed in 1848; but owing to defective construction it was found inoperative. It

was followed, in 1849, by a second act (12 and 13 Vict. c. 77), the object of which was to enable any owner of land, or of a lease of land for not less than 63 years unexpired, subject to incumbrance, to apply to commissioners, appointed under it, and forming a court of record, to direct a sale. The total number of petitions presented in the eight years ending 1857 was 4,413, of which 1363 were lodged by owners. The number of absolute orders for sale during the same period was 3,547. The gross amount produced by sales from the foundation of the court up to Aug., 1859, was £25,190,839, of which there was distributed to creditors £24,229,027, including £3,692,611 allowed to incumbrancers who became purchasers. A sum of £961,809 remained in hand to satisfy unadjusted claims. At this period, however, the business before the court had almost ceased. There were, in fact, no longer mortgagees exasperated by long-suffering left to petition; all the incumbered land had been sold, and everybody with claims on it had been paid. It was then determined that the new tribunal should, with wider functions, be rendered permanent. The landed estates (Ireland) act (21 and 22 Vict. c. 72), passed in 1858, abolished the incumbered estates court, and transferred the judges and officers to the landed estates court, a permanent tribunal, with the wider functions required, and with various other powers connected with the declaration of title, partitions, exchanges, and redistribution of land. The record of title office, the counterpart of the land registry office in England, has been since placed under the direction of the landed estates court. Since the passing of the act in 1865 to Nov., 1871, 493 estates had been registered, valued at £1,715,870, the amount of mortgages recorded being £177,344. Between Nov. 1, 1858, and Jan. 31, 1862, the amount realized by sales made by the landed estates court was £5,940,990; and the approximate capital value of estates brought under its jurisdiction, but remaining unsold, £3,664,996. The rental and value of the estates sold in 1870, 1875, and 1877 are indicated in the following summary:

	1870.	1875.	1877.
Net rental of estates sold	£46,269	£63,292	£74,300
Amount of purchase money	757,218	1,209,488	1,430,453
Number of sales	201	258	310

There can be no doubt that the statutes calling into existence these courts have facilitated a great revolution in the tenure of the land in Ireland. They supplied the means by which a very great part of the soil passed rapidly from cottier tenants (i.e., laborers paying rents determined by competition) and an embarrassed and non-resident gentry to capitalist farmers and to landlords who cultivated the soil themselves, and under whom the country rapidly increased in agricultural prosperity. There can be as little doubt, however, that the process inflicted grievous injury on the tenants. It had never been usual in Ireland, as in other countries, for the landlord to bear the expense of permanent improvements. These were carried out by the tenant, who trusted to make an arrangement with regard to rent which would compensate him for his expenditure of labor or money. The sales under the incumbered and landed estates acts deprived the tenant of all power to make such claims. Increased rents were demanded under pain of eviction, and the result was that small farmers were obliged to emigrate, to remove to the towns in search of work, or remain as servants on their old farms. The Irish peasantry were not a class likely to submit quietly to such changes. Acts of retaliation and widespread discontent were the consequences, and it was found necessary to reconsider the whole subject of land tenure in Ireland. The conclusion come to was that exceptional legislation was necessary for this part of the United Kingdom; and accordingly on Aug. 1, 1870, the Irish land act was passed, which effectually checked what was described as the grievous wrong and injustice to tenants by the purchasers in the land courts. It would at present be premature to express any opinion as to the ultimate effect of the new land law on the political and social condition of the Irish people.—See *The Story of the Incumbered Estates Court*, by Percy Fitzgerald, 1862; article on the new Irish land law, in *Fraser's Magazine* for Mar., 1872; and Thom's *Irish Almanac*, which gives annually a summary of the information contained in the return made to the house of commons.

In 1854 the West Indian incumbered estates court was established under the statute 17 and 18 Vict. c. 117, entitled "an act to facilitate the sale and transfer of incumbered estates in the West Indies." The purposes and regulations were similar to those of the Irish incumbered estates act, the court of the chief commission being held, however, in Westminster, where it still sits

INCUM'BRANCES, a general term for burdens or charges on land. See HERITABLE SECURITIES, MORTGAGE, LIEN; INCUMBERED ESTATES COURTS.

INCUNAB'ULA, a Latin word signifying cradle, is employed by bibliographers to designate the first fruits of the art of printing; the books which, as Peignot has it, *touchent au berceau de l'imprimerie*. The term is usually restricted to those which appeared before the year 1500, by which time the art was completely formed in all its principal departments. The number of these works is probably not far short of 20,000. Hain, it is true, in his *Repertorium Bibliographicum*, enumerates only 16,299; but as he unfortunately died before his work was completed, it is confessedly imperfect, especially in the last volume.

Incunabula, with hardly any exceptions, belong to the category of rare books, and are therefore much sought for by collectors; but besides the interest attaching to them as lit-

erary curiosities, many of them, such as the first editions (*editiones principes*) of the Greek and Roman classics, are intrinsically valuable in a critical point of view; whilst others are important, as marking the successive steps by which the art of printing advanced towards perfection. Information as to these particulars will be found in the article PRINTING.

The principal works treating specially of incunabula are—Panzer, *Annales Typographici, ab Artis Inventæ Origine ad Annum M.D.* (continued, however, to 1536), 11 vols. 4to, Norimbergæ, 1793–1803; Maittaire, *Annales Typographici, ab Artis Inventæ Origine ad Annum* 1557 (*cum Appendice ad Ann.* 1664), 3 tom. in 5 vols. 4to, Hagæ-Comit. 1719–25; Serna Santander, *Dictionnaire Bibliographique Choisi du XVe Siècle*, 3 tom. 8vo, Bruxelles, 1805–7; and Hain, *Repertorium Bibliographicum, quo Libri omnes ab Arte Inventa usque ad M.D. Typis Expressi recensentur*, 4 tom. 8vo, Stutgartiæ, 1828–38. With all its imperfections the last is the best work we have on the subject. Much valuable information will also be found in Bernard, *De l'Origine et des Débuts de l'Imprimerie en Europe* (1853); and, on French incunabula, in Brunet's *La France Littéraire au XVe Siècle* (1865).

INDEBITATUS ASSUMPSIT, the name often given to an action for debt in England.

INDECENT EXPOSURE is a criminal offense both at common law and in England and Ireland also by statute. It is not clearly settled whether more than one person must have witnessed the indecency, in order to make it an offense. The exposure must be in some public place. By the statute 5 Geo. IV. c. 83, s. 4, the offense is punishable summarily by three months' imprisonment. To sell or expose an obscene book, print, or picture, is also punishable by fine and imprisonment and hard labor; and a warrant can be obtained under 20 and 21 Vict. c. 83, to search premises, and seize and destroy such books, etc. In Scotland indecent practices are also indictable offenses, but the law is somewhat vague, and the punishment left to the discretion of the court.

INDEMNITY DEED, in English law, is a deed given by way of security. The usual form of indemnifying a person is by giving a bond of indemnity, which operates if the engagement is not fulfilled, but otherwise becomes void. A similar bond is called generally a bond of relief in Scotland.

INDENTED, in heraldry, one of the partition lines of the shield, similarly notched to dancetté (q.v.), but with the notches much smaller, and not limited in number.

INDENTED HEAD, a peninsula in the colony of Victoria, bounds the entrance to Port Phillip on the west.

INDENTURE, the technical name given in England to a deed under seal, entered into between two or more parties with mutual covenants. Formerly it required to be actually indented—i.e., notched or toothed (Lat. *dent*, tooth), or cut in a waving line, so as to correspond with the other copy of the deed—but this is no longer necessary. The name is not used in a general sense in Scotland, except in the case of indentures of apprenticeship (q.v.), though in England it is a synonym for the kind of deeds mentioned.

INDEPENDENCE, a n.e. co. of Arkansas, traversed by the White river; 1010 sq.m.; pop. '70, 14,566. The surface is uneven. The soil is fertile, producing grain, cotton, tobacco, maize, hay, and cattle. It abounds in timber, and has valuable minerals.

INDEPENDENCE, a city in Buchanan co., Iowa, on the Wapsipinicon river, and at the junction of the Illinois Central and Burlington, Cedar Rapids, and Minnesota railroads, 65 m. w. of Dubuque; pop. '70, 2,945. It has 2 banks, 9 churches, 10 public schools, 2 newspapers, 3 fire-companies, several fine parks, and extensive fair-grounds. It is the seat also of the state insane asylum, which in 1873 contained 113 patients, and whose erection cost nearly $1,000,000.

INDEPENDENCE, a city of Jackson co., Mo., on the Union Pacific railroad, 4 m. s. of Missouri river, 10 m. e. of Kansas City, and connected with it by a railroad; pop. '70, 3,184. It has 2 banks, 2 newspapers, 3 hotels, several public schools, and 2 colleges. It was settled in 1827, and was formerly the rendezvous for the emigrant trains from the e. to California, Oregon, New Mexico, and Utah, and was occupied in 1831 by the Mormons, who were expelled in 1838 and settled in Illinois, and afterwards in Utah.

INDEPENDENCE, a t. of Washington co., Texas, 80 m. e. of Austin, 25 m. from Hempstead, on the Houston and Texas Central railroad, 12 m. from Brenham, on the w. branch of that road; pop. 1000. It has public schools, several churches, is the seat of Baylor university, and Baylor college for women, controlled by the Baptists. The university has a theological department, with 5 professors, 80 students, and a library of 2,700 volumes.

INDEPENDENCE, DECLARATION OF. See DECLARATION OF INDEPENDENCE.

INDEPENDENCE OF STATES, a term applied to states which by international law are self-governing as to their internal affairs, and also perform international acts towards other states. None of the United States being absolutely self-governing, and none having any international character, none is independent.

INDEPEN'DENTS, or CONGREGA'TIONALISTS. The distinctive principle of the Congregational church polity is that every Christian church or congregation is entitled "to elect its own officers, to manage all its own affairs, and to stand independent of, and irresponsible to, all authority, saving that only of the Supreme and Divine Head of the Church, the Lord Jesus Christ." They regard the sacred Scriptures as their only standard, and hold that human traditions, fathers and councils, canons and creeds, possess no authority over the faith and practice of Christians. Congregationalism denies that there is any authority in Scripture for uniting the churches of a nation or province into one church or corporation to be ruled by a bishop or bishops, superior to the bishops or pastors of particular congregations, or by a presbytery or synod consisting of the pastors or elders of the several congregations of the nation or province. This is the speciality which distinguishes Independency or Congregationalism from Episcopacy and Presbytery. The term "Independent" is supposed to have originated in the incidental use of the word in an "apology" addressed in Latin and English to the British and Continental universities, about the year 1604. But the early maintainers of this form of church government were careful to repudiate certain inferences which might be drawn from the use of the word. "We do profess dependence," said one of them, "upon magistrates for civil government and protection; dependence upon Christ and his word for the sovereign government and rule of our administrations; dependence upon the council of other churches and synods, when our own variance or ignorance may stand in need of such help from them." The independence claimed was only the right of every individual church to administer its own affairs, free from the control or authoritative jurisdiction of other churches—a right compatible, it was asserted, and is still asserted, with union for the promotion of common ends, and with fraternal aid and council in cases of variance or other difficulty.

Doctrinally, the early Independents occupied the same position as the other sections of the Puritan family. They held in substance the evangelical doctrines of the Reformers, of the Westminster assembly, and of the thirty-nine articles. While declining subscription, and frankly tolerant of very considerable diversities of opinion, modern Congregationalists profess to be of one mind in regard to the cardinal truths of Christianity.

For the history of this body we must refer to the works named at the end of this article. But it may be mentioned that as early as the days of queen Elizabeth they were numerous and influential. In a speech made by sir Walter Raleigh in the house of commons in 1592, on the subject of a law to transport the Brownists —as they were offensively and untruly named—he thus refers to their numbers: "If two or three thousand Brownists meet at the sea-side, at whose charge shall they be transported? or whither will you send them? I am sorry for it, but I am afraid there is near twenty thousand of them in England; and when they are gone, who shall maintain their wives and children?" Several eminent men of this body suffered death for their opinions; others were condemned to banishment. The greater part retired to Holland. Numbers sought an asylum in New England; and America still cherishes the memory of the Pilgrim Fathers as the founders of those institutions which are the sources of her freedom, her intellectual and moral power, and her national elevation.

By the passing of the act of uniformity in 1662, the Independents, along with other nonconformists, were subjected to much suffering. The act required an express assent and consent to everything contained in the revised prayer-book, and its effect was to cause 1900 or 2,000 of the clergy to leave the church. Still the Independents increased; and the revolution of 1688, and passing of the toleration act in 1689, at length brought them relief. Efforts were made about this time to bring about an accommodation between them and the English Presbyterians; and in 1691 heads of agreement were drawn up, but with little practical result. In 1730 Presbyterians, Baptists, and Independents formed themselves into a united body, under the name of the three denominations, for the protection of their civil and religious liberties. The Independents are the largest dissenting body in England except the Wesleyan Methodists. By the census of 1851 the number of their churches in England and Wales is given at 3,244, with accommodation for 1,067,760 persons, and an estimated attendance of 793,142 (see article GREAT BRITAIN). There has been no general religious census since 1851, but it is well known that the Independent body has very largely increased. The largest confederation of its churches is "the Congregational Union of England and Wales," which is careful to lay down in its basis the principle that "it shall not, in any case, assume legislative authority, or become a court of appeal."

An Independent church is, from its very constitution, at liberty to choose any man for its minister whom it considers qualified for the office—subject only to the check arising from the fact that neighboring ministers will refuse to ordain or recognize a man whom they have reason to regard as disqualified. But from the beginning the Independents have attached great importance to an educated ministry. Their leaders in the Puritan age, such as Owen, Howe, and Greenhill, were men of great learning, and, as soon as the act of toleration in 1689 allowed, measures were taken for securing a succession of educated men. They have now eleven theological colleges in England and Wales. These are (with the number of students in 1876):

	Date of Formation.	No. of Students.
Western college, Plymouth	1752	15
Rotherham college	1756	14
Brecon college	1760	35
Airedale college, Bradford	1784	14
Hackney college	1796	20
Lancashire college	1806	47
Spring Hill, Birmingham	1838	13
New college, London	1850	43
Bala college	1842	30
Bristol institute	1863	14
Nottingham institute	1863	44

In this list "New college" is a union of three older colleges, Homerton, Highbury, and Coward. The college at Cheshunt, belonging to lady Huntingdon's trustees, was founded for the preparation of young men for the Christian ministry, in any section of the church to which they might be called. But it is virtually an independent college—all its present professors and almost all its students being Independents. The "Carmarthen Presbyterian college," though governed by Dr. Williams's trustees who are Unitarians, has an Independent for its theological professor, and 28 Independent students. The Congregationalists of Scotland have a theological hall in Edinburgh. There are two colleges in Australia and one in Canada.

In Scotland Independency may be traced back to the days of the commonwealth, during which it was imported by the chaplains and soldiers of Cromwell. But the present Independent churches in Scotland owe their origin mainly to a missionary movement in the end of the last century chief among the leaders of which were the brothers Robert and James Haldane, Graville Ewing, John Campbell, and John Aikman. The Haldanes became Baptists in course of time—a circumstance which greatly divided and weakened the new community. The formation of an academy for the training of ministers in 1811, and of the Congregational union about the same time, did much to restore the lost vigor of the body. There are about 100 churches at present in this "union." It should be added that the Baptist churches, both in England and Scotland, are as strictly "Independent" as those which bear that name.

In America the first Independent church was founded by John Robinson at Plymouth, New England, in 1620. In 1637 the spread of Antinomian doctrine caused much discussion in the church. By a synod convened in New England Antinomianism was unanimously condemned. In 1638 Harvard college was founded. In 1658 the Savoy confession was adopted. It still remains in force. About 1750 Unitarian principles spread widely in the Congregational churches of America. In 1785 a separation took place between the Unitarians and the Trinitarians, but both still retain the Congregational form of church government. Harvard college is Unitarian. "Congregationalism," according to Dr. Schaff, "is the ruling sect of the six north-eastern states, and has exerted, and still exerts, a beneficial influence upon the religious, social, and political life of the whole nation." At present the number of Congregational churches in the United States is upwards of 2,500, with more than 320,000 church-members, and nearly 400,000 children in Sabbath-schools. Exclusive of Harvard and other colleges, in the administration of which they have a share, the American Independents possess theological seminaries at Andover, Bangor, New Haven, Oberlin, Hartford, Oakland (California), and Chicago. The reader may consult the following works with advantage: Dr. Vaughan's *History of English Nonconformity;* J. Fletcher's *History of Independency;* Waddington's *Early History;* Hanbury's *Memorials;* Neal's *History of the Puritans;* Dr. Stoughton's *Ecclesiastical History of England;* and Mosheim's *General Church History.*

INDEPENDENTS (*ante*). See CONGREGATIONALISM.

INDETERMINATE PROBLEMS. It was shown in the article EQUATIONS that the values of the unknown quantities could only be determined when the number of equations was equal to the number of unknown quantities, but that, if the latter exceeded the former, *several* values might be found for each unknown, in which case the problems which give rise to the equations are called *indeterminate problems.* For example, "To find the number which, when divided by 2 and 3, leaves remainders 1 and 2," is an indeterminate problem, admitting of an infinite number of solutions; for though only one unknown quantity appears in the question, yet, in order to form an equation, we are obliged to proceed in the following manner: as x is divisible by 2, with a remainder 1, $x = 2p + 1$; again, as x is divisible by 3, with a remainder 2, $x = 3q + 2$; hence we have the equation $2p + 1 = 3q + 2$ (one equation to find two unknown quantities), from which, by a process which is explained in the ordinary books on algebra, we find $x = 6r - 1$, where r is any positive number whatever. The values of x are, therefore, 5, 11, 17, 23, etc. In general, if the equation is of the form $ax + by = c$, the number of pairs of values (of x and y) is finite; but if of the form $ax - by = c$, the number is infinite. The Diophantine (q.v.) analysis exhibits a very interesting class of indeterminate problems of the second degree.

INDEX (more fully INDEX LIBRORUM PROHIBITORUM), a catalogue published by papal authority in the Roman Catholic church of books the reading of which is prohibited to members of that church, whether on doctrinal, moral, or religious grounds. As a natural consequence of the claim of the Catholic church to authority in matters of religion, and to infallibility, that church also claims the right or the duty of watching over the faith of its members, and of guarding it against every danger of corruption, the chief among which is held to be the circulation of books believed to be injurious to faith or to morality. The earliest recorded exercise of this restrictive authority is the prohibition of the writings of Arius; and a council of Carthage, in the year 398, issued, even for bishops, a similar prohibition of gentile books, although it permitted to them the reading of the works of heretics. The earliest example of a prohibitory catalogue is found in the decree of a council held at Rome (494) under pope Gelatius (*Labbe Conc.*, ii. col. 938–41), which, having enumerated the canonical books of Scripture and other approved works, recites also the apocryphal books, together with a long list of heretical authors, whose writings it prohibits, and orders to be eliminated from the churches. The mediæval popes and councils pursued the same course as to the heterodox or dangerous writings of their respective periods, and the multiplication of such books after the invention of printing led to a more stringent as well as more systematic procedure. The university press of Louvain issued in 1546, and again in 1550, a catalogue of prohibited books. Similar lists appeared by authority at Venice, Paris, and Cologne; and Pius IV. issued in 1557 and 1559 what may be regarded as properly the first Roman Index. One of the gravest undertakings of the council of Trent was a more complete and authoritative enumeration of all those books the use of which it was expedient to prohibit to the faithful. A committee was appointed for the purpose, and had made great progress in the work; but it was found impossible to bring the examination of the books to an end before the close of the council; and the entire of the papers of the committee were handed over by the council to the pope, with instructions that the work should be completed, and the result published by his own authority, which was accordingly done by Pius IV. in 1564. Further additions and certain modifications of its rules were made by Sixtus V. and Clement VII. It was republished in 1595, and with the addition of such books as from time to time it was deemed expedient to prohibit, in several subsequent editions, the most remarkable of which are those of Brasichelli (Rome, 1607); Quiroga, *Index Librorum Expurgandorum* (Salamanca, 1601); and Sotomayor, *Novissimus Index* (Madrid, 1648). The edition best known to modern theological readers is that of Rome, 1819. In the intervals between the editions, the decrees by which further additions to the Index are made, are made public at Rome, and circulated in the various countries.

The prohibitions of the Roman Index are of two classes, either absolute and total, or partial and provisional, "until the book shall have been corrected." The edition of Quiroga, mentioned above, regards the latter. The ground of the prohibition may be either the authorship of the work, or its subject, or both together. Under the first head are prohibited all the writings of *heresiarchs*—i.e., the first founders of heresies—no matter what may be the subject. Under the second head are prohibited all books confessedly immoral, and all books on magic, necromancy, etc. Under the third are prohibited all books of heretical authorship treating on doctrinal subjects; all versions of the Bible by heretical authors; and all books, no matter by whom written, which contain statements, doctrines, or insinuations prejudicial to the Catholic religion. The preparation of the Index, in the first instance, was committed to the care of the congregation of the inquisition in Rome; but a special congregation of the Index was established by Pius V., and more fully organized by Sixtus V. This congregation consists of a prefect (who is always a cardinal), of cardinals, of consulters, and of examiners of books (*qualificatores*). Its proceedings are governed by rules which have been authoritatively laid down by several popes, especially by Benedict XIV., in a constitution issued July 10, 1753, to which the reader is referred for the best and most authentic exposition of a subject on which much misconception exists on the part of Catholics as well as of Protestants.

The growth of modern literature has, of course, entirely outstripped the limited and tardy machinery of this tribunal. A very small proportion even of the most anti-Catholic publications outside of Italy find their way by name to the Roman Index; but besides the positive prohibitions of the Index itself, there are certain general rules regarding the use of books by which the freedom of what is considered perilous or pernicious reading is much limited among members of the Roman Catholic church. These, however, would be entirely beyond the scope of our publication; nor could the rules of the Index even be practically brought into operation in those countries where the Catholic and Protestant literatures are so interwoven, that it is impossible to separate them even in the ordinary intercourse of life. See Wetzer's *Kirchen-Lexicon*, art. "Index."

Few parts of the Roman Catholic system are more repugnant to intelligent Protestants than the institution of the "Index," as it strikes at the root of the fundamental principle of Protestantism itself—namely, that of private judgment. And this theoretical repugnance is increased by seeing that, in its practical working, such names as Gibbon, Robertson, Guicciardini, Sismondi, Hallam, Goldsmith (*History of England*), Des-

cartes, Locke, Kant (*Essay on Pure Reason*), J. S. Mill (*Political Economy*), Whately (*Logic*), Bacon, Milton, Addison, Dante (*De Monarchia*), etc., are put under the ban.

INDIA,* an extensive region of southern Asia, celebrated during many ages for its riches and valuable natural productions, its beautiful manufactures and costly merchandise, the magnificence of its sovereigns, and the early civilization of its people. It possesses especial interest to the Englishman, from the intimate connection of its history with that of his own country.

Hither India is the central peninsula of southern Asia, and lies in 8° 4′ to 35° n. lat., and 67° to 92° e. long. According to these limits, its length may be stated approximately at 1900 m., and its breadth, reckoned along the parallel of 25° n. lat., at 1600 m., with an area of about 1,300,000 sq. miles. The natural boundaries of this vast region are, on the n., the range of the Himalaya mountains, which separates it from Tartary, China, and Thibet; on the w., the Suliman mountains divide it from Afghanistan and Beloochistan; on the s., the Arabian sea and the gulf of Bengal; and on the e., the hill-ranges which separate Chittagong and Assam from Burmah. From the mouths of the Brahmaputra and the Indus, the e. and w. coasts, inclining towards the same point, meet at cape Comorin, and thus give to southern India the form of an irregular triangle. The two sides of the triangle have each a coast-line of about 2,000 miles. India is, in fact, from its great extent of seaboard, essentially a maritime country.

Further India is the name given to the south-eastern peninsula of Asia. It is not treated of in this article, and for information concerning it reference is made to the articles on SIAM, BURMAH, COCHIN-CHINA, etc.

Physical Features.—Hither India presents a most diversified surface and varied scenery; it has indeed been called "an epitome of the whole earth," consisting as it does of mountains far above the level of perpetual snow; broad and fertile plains, bathed in intensest sunshine, arid wastes, and impenetrable forests. Its great natural divisions are the sub-Himalayan countries, the plain of the Ganges, the plain of the Indus, the highlands of northern Hindustan, and the peninsular portion of the country to the s. of the Vindhya mountains.

The sub-Himalayan Countries form an elevated tract lying between the chief ridge of the Himalayas and the lower elevations which adjoin the plains of the Ganges and Indus. They consist of Cashmere, Gurhwal, Kumaon, Nepaul, Sikkim, and Bhotan, all hill-countries, which, owing to their elevation above the sea, have a cool climate and the vegetation of the temperate zones. These regions are separated from the plain of the Ganges by the Terai, or Great Indian swamp, which extends in a long belt, 5 to 25 m. in width, from Hurdwar to the Brahmaputra. It is covered with great forest trees, and is the haunt of innumerable wild beasts. The soil is very fertile, but malaria renders it uninhabitable by man and the domestic animals, at least from April to Oct. It is then said to be abandoned even by the wild beasts. This wilderness forms a great physical barrier between the hill-countries and the plains, and separates populations distinct from each other in race and language.

The Plain of the Ganges, which includes Bengal, Bahar, the Doab, Oude, and Rohilcund, is a vast alluvial flat, extending from the bay of Bengal to the Punjab. Throughout its entire length, the Ganges and its numerous tributaries spread out like the veins of a leaf, carrying everywhere their fertilizing influence. The population of these fertile and well-cultivated plains is very dense. Scattered over the agricultural districts, and massed in the great cities and towns, there are not less than 100,000,000 people.

The Plains of the Indus, in the n.w., are less extensive than those of the Ganges, and are separated from the latter by the Aravulli hills. The Punjab occupies the northern portion. South of the Punjab, and parallel with the river, the great sandy desert of the Indus extends for nearly 500 miles. The valley of the Indus is continued through Sinde to the ocean. The plains of the Indus may be considered to include Cutch and Gugerat, which like them slope towards the Arabian sea. Between the Indus and the Aravulli mountains lies the Thur or Indian desert, an expanse covered with sand-hills, 400 m. long and 100 broad. It is only in the neighborhood of the Indus and the Luni that the surface can be cultivated—although crops of grain may be grown in a few narrow valleys after the rains. The horse and camel alone can cross this desert, which is described in Hindu geography as "the region of death." Like the Terai, it forms a great physical barrier separating western and eastern India.

The Highlands of Northern Hindustan extend from the Vindhya mountains as a base to the border of the Thur. They include the table-land of Marwa and Rajpootana or Rajasthan, which has an elevation of about 2,000 ft. above the level of the sea.

The Peninsular Portion of India, s. of the Vindhya mountains, which remains to be considered, is called by the natives the Deccan (q.v.). The most remarkable geographical feature of this area is a central table-land—a vast plateau—extending from 12° to 21° n. lat., rising from 2,000 to 3,000 ft. above the sea, and inclosed on all sides by lofty

* The name is borrowed by the Greeks from the Persians, who, however, applied the name of Hindus at first only to the dwellers on the banks of the river *Sindhu* (Sans. for Indus). From this, by the regular change of *s* into *h*, the Persian *Hind* is derived. Hindustán (the country of the Hindus) is a modern word applied by the Persians to the whole of India; but Europeans understand it as applying properly to that portion of it which lies n. of the Vindhya mountains.

mountains, between which and the sea, on the e. and w., are narrow strips of low flat country, divided into several districts. From the low country on the coast to the central table-land the mountains rise abruptly, in a succession of gigantic terraces or steps, and hence the name of "Ghauts" (q.v.). The rivers of the Deccan rise in the western Ghauts, and after transversing the table-land, descend to the sea over the eastern Ghauts. The slope of the country corresponds with the course of the rivers; it has a gradual inclination towards the east. Ceylon, the Lacadive, and Maladive islands may also be considered to belong to this part of India.

The *Himalaya* (q.v.) and the *Suliman* mountains (see AFGHANISTAN) far exceed in altitude the chains which lie within the boundaries of India. The *Vindhya* mountains, which cross India between 22° and 25° of n. lat., and separate Hindustan proper from the southern or peninsular portion of the country, nowhere exceed 6,000 ft. in height. The Satpura range, between the Nerbudda and Tapti valleys, is a spur of the Vindhya. The *Western Ghauts* run parallel with the Indian ocean at a distance of 20 to 40 miles. At Mahabaleshwar, the sanitarium of Bombay, they rise to 4,500 ft., but they are lofty near Coorg, where one summit has an elevation of 7,000 feet. On the opposite coast, forming the south-eastern buttress of the table-land of the Deccan, are the *Eastern Ghauts* (see GHAUTS). The physical geography of southern India presents the singular phenomenon of isolated masses upheaved amidst the vast plains that occupy the greater portion of the peninsula. Of these, the most remarkable are the Neilgherries (q.v.) or Blue mountains, which cover an area of 600 sq. miles. Ootacamund (q.v.), the great sanitarium of southern India, situated in the midst of them, has an elevation of 7,400 feet. Of the minor mountain-ranges of India, the principal are the Sewalik range, near Hurdwar, rising 3,000 ft.; the Kala or Salt range, adjacent to the Suliman range, rising 2,500 ft.; the Aravulli, between the basins of the Ganges and the Indus, culminating in Mt. Abu at an altitude of 5,000 ft.; the Kattywar hills, rising from 1000 to 3,000 ft. in the center of the Kattywar peninsula; the hills of Bundelcund, 2,000 ft.; and the Rajmahal hills, rising from 5,000 to 7,000 feet.

The *river-system* of India is on a grand scale. The Indus (q.v.) traverses the n.w., and drains about 400,000 sq.m. of country. The Ganges (q.v.), on the n.e., together with its tributaries, drains an area of about 500,000 sq. miles. The Brahmaputra (q.v.) has a course of upwards of 600 m. from the point where it leaves the Himalayas to that where it enters the bay of Bengal. The eastern side of India—the region southward of the Nerbudda, and eastward of the Malabar Ghauts—is watered by 18 rivers, the principal being the Godavery, 830 m. long; Kistna, 800; Cauvery (Kaveri), 470; Mahanadi, 520; Brahmini, 400; North Pennar, 350; and the South Pennar, 240. About 20 rivers water the western side of India. The most noteworthy are the Nerbudda, 800 m. long; the Tapti, 490—both of which flow into the gulf of Cambay; the Myhi, 350 m.; Luni, 320 m.; Bunnas, 180 m.; and the Bhadro, 130 miles.

Geology.—From observations that have been made at different points in India, the general features of its geological structure are known. A staff of geologists commenced more than a quarter of a century ago a geological survey of India, which has since then been uninterruptedly proceeded with. They have already examined an area more than four times as large as that of Great Britain, and their inquiries have supplied, for the districts they have dealt with, an accurate knowledge of the mineral resources of India.

India is bounded on the n.e. by the range of the Himalayas, the great water-shed of central Asia. These mountains consist of granitic rocks which have penetrated the stratified rocks, thrown them up in endless confusion, and metamorphosed them in many places into gneiss, mica-schist, clay-slate, or crystalline limestone. Layers of sandstone and conglomerate extend along the base of the mountains. They are of the miocene age, containing the remains of species of camel, giraffe, hippopotamus, sivatherium, elephant, crocodile, and tortoise. These are extensively developed in the Sewalik hills. An immense tract of post-tertiary alluvial deposits covers the whole of the river-basins of the Ganges and the Indus, stretching across the n. of India from sea to sea. The eastern and western Ghauts consist of metamorphic rocks, which are continued across the country to the n. of the Godavery. Between this transverse band of altered strata and the diluvial deposits of the n., a large tract of country is occupied with palæozoic rocks, frequently broken through and covered with different kinds of trap, and in some places overlaid with secondary and fresh-water tertiary strata. One of the most important labors of prof. Oldham and his geological staff has been the exploration of the great Indian coal-fields. They lie in a region bounded by the Ganges on the n., and extending beyond the Godavery on the south. The coals come from one geological formation called "Damuda," from the river Damodar, in the valley of which the chief beds occur. It differs little geologically from the carboniferous beds of England. Iron, copper, and lead are worked in different parts of India. Salt is obtained from the Salt range above referred to, and produced abundantly by evaporation in the salt lakes of the Thur.

Vegetable Productions.—The vegetation of India is as varied as its soil and climate, and passes from the flora of a tropical to that of an alpine region. The groves of palm that border the coast, and, in the interior, the umbrageous mango topes, are striking features of Indian scenery. Rice is the chief article of food in India, and is produced in

all the parts of the country in which irrigation is practiced. Maize and wheat are the grains cultivated in the n.w. provinces. Opium is one of the most valuable products of India. In 1871–72 the value of the chests exported from Bombay and Calcutta to China was £6,850,000. Coffee is largely produced in Ceylon, and the cultivation of the plant is rapidly spreading in southern India. Tea cultivation is now carried on with success in Assam, and is spreading over all the hill-countries of n.w. India. Cinchona, introduced from South America in 1860, has been naturalized with great success. The cost of doing so was £61,719. "The return," Mr. Markham says, "represents a value which is simply incalculable and without price;" a cheap supply of quinine being one of the most certain means of averting the fevers that prevail in the hot and moist parts of India. As a commercial speculation the measure ultimately will prove highly remunerative. The growth of cotton has been much extended since the American war. The finest is produced in Berar. The rhea, or jute plant, is grown in Assam and Bengal, and has recently given rise to an important trade. India-rubber is another important product of Assam, the demand for which is increasing. Within the last 15 years great attention has been paid to the importance of preserving the Indian forests. The destruction of the woods was found to give rise to destructive floods, and to render the water-supply uncertain and capricious during the dry season. The Indian cultivators have been rapidly improving in prosperity, and with that improvement there has been an increasing demand for timber for house construction and furniture—a demand further augmented by the requirements of the railways. In order to protect existing forests, and extend the area of the timber-producing districts, the Indian forest conservancy department was organized, the main objects of which were the definition and demarkation of reserved forests, and the prevention of jungle fires—that is to say, of the native practice of burning forests for cultivation, and the cutting and clearing away of creepers round the young trees. The system of preparing candidates for forest service was commenced in 1867, when the first examination was held by the civil service examiners. Since that time, a large number of officers who have studied forestry in England, Germany, and France have been sent to India, and great satisfaction has been expressed with the work they have done.

Animals.—The domesticated animals are horses, asses, mules, oxen, buffaloes, sheep, and elephants. Of wild beasts the most formidable is the Bengal tiger. The other beasts of prey are leopards, wolves, jackals, panthers, bears, hyenas, lynxes, and foxes. Of poisonous snakes the cobra da capello, or black-hooded snake, the cobra manilla, and sand-snake are the most common. The number of people killed by wild beasts is a feature of Indian life. In 1869 a tigress killed 127 people, and stopped a public road for many weeks. In 1871, 14,529 were known to have lost their lives in that year by snake-bites. In 1871 the total number of deaths known to have been caused by dangerous animals of all classes was 18,078. It is believed that if systematic returns were kept, the number in British India would be found to exceed 20,000.

Climate.—In a country extending over 26° of lat.—one extremity of which runs far into the torrid zone, and the other terminates in a range of lofty mountains rising far above the line of perpetual snow—a country embracing within its ample circumference lowland plains, elevated plateaux, and alpine regions, the climate must differ greatly. Hindustan proper may be said to have three well-marked seasons—the cool, the hot, and the rainy. The cool months are Nov., Dec., Jan., and a part of Feb.; the dry hot weather precedes, and the moist hot weather follows, the periodical rains. The climate of southern India is greatly regulated by the monsoons (q.v.). The central table-land is cool, dry, and healthy. At Ootacamund, on the Neilgherries, 7,300 ft. above the level of the sea, the mean annual temperature is 57° F.; at Madras, 82°; Bombay, 84°; Calcutta, 79°; Bangalore, 74°; and at Delhi, 72°. The fall of rain varies greatly in different parts of India. A map of the Indian rainfall given by Mr. Markham in his report, published in 1873, shows that in the whole of n.e. India, from the valley of the Sutlej to the mouth of the Irrawaddy, including the sub-Himalayan countries, Assam, and British Burmah, and between the western Ghauts and the Coromandel coast, exceeds 75 inches. In the interior of the Deccan it is less than 30, and in Multan and Sinde less than 15 inches. The remainder of India is placed between the extremes represented by these damp and dry belts, but is, as compared with Europe, an arid country. Hence the necessity of tanks and irrigation canals to supply moisture to the soil, and to obviate the danger of dry seasons.

Inhabitants.—Three races widely distinguished from each other inhabit India. In the n.e. are Mongols, resembling the Thibetans and Burmese; in the s., Dravidians, the relation of whom to other great branches of the human family is still a subject of dispute; and in the n.w., Aryans. It is supposed that at a remote epoch a branch of the Aryan race (q.v.) entered the peninsula from the n.w., established themselves first in the Punjab, and thence gradually diffused themselves as a dominant race over the whole of northern and central India, imbuing the subject population more or less completely with their religious system and their language, and thus forming the Hindus. Tribes still inhabiting the mountainous districts and jungles are supposed to be outstanding islands of the aboriginal population that resisted the tide of Hindu conquest and civilization. The Hinduizing influence extended feebly, if at all, into the Deccan, the great majority of whose inhabitants, therefore, are supposed not to belong ethnologically to the Aryan race.

Professor Friedrich Müller thus distributes the Indian races according to their languages (see also the *Geographical Magazine* for Jan., 1878).

A. *Mongols*—(1) Thibetans, subdivided into Thibetans proper, in upper terraces of the Himalayas; and, s. of them, the sub-Himalayan tribes, speaking Lepcha, Kiranti, Limbu, Murmi, etc. (2) The Birman or Lohitic races, speaking Burmese, of Aracan, Kooch, Dhimal, Bodo, Garo, Miri, Singpho, Naga, Kuki, etc. (3) The Thai, or Siamese races, speaking Ahom (Assam), Khamti, etc.

B. *Dravidians*, subdivided into—(1) The Munda branch—Kol (in Chota Nagpore), Sontal, Ramusi, Warali, Bheel, etc. (2) The Dravida branch proper—Tamul, Telinga, Canarese, Malayala, Tulava, Toda, Gond, Khond, Rajamahal, Kol, Brahui (in Beloochistan). (3) The Singhalese branch in Ceylon, including the Veddahs. The Tamul, Telinga, Canarese, Malayala, Tulava, and Singhalese are spoken by cultivated races; the other languages by rude hill-tribes.

C. *Aryans*, subdivided into—(1) The races of Dardistan and the n.w. frontier, including the Siah-posh Kaffirs, and other rude tribes. (2) The Hindus, including the cultivated races speaking the following languages: Cashmiri, spoken in Cashmere; Punjabi, in the Punjab; Hindi, in various dialects sometimes described as languages, spoken in the western plain of the Ganges and Malwa; Sindhi, in Sinde; Cutchi, in Cutch; Gugerati, in Gugerat; Mahrati, in the n.w. Deccan, s. of the Vindhya mountains; and Bengali, spoken in the plain of the Ganges, e. of the bend of the river at Rajmahal; and the Orya, Assami, and Nepauli, all resembling the Bengali, and spoken in Orissa, Assam, and Nepaul by the Hindu section of the inhabitants. For an account of the connection of these languages with the old Prakrit dialects of India, see SANSKRIT and PALI.

The word Hindu is used in various senses, and it is important to guard against the confusion that may thence arise. It is applied (1) to the people speaking the Hindi dialect of the North-western Provinces; (2) to the Aryans of northern India; (3) to the cultivated races of India, both Aryan and Dravidian, who profess the Hindu religion, and have been influenced by the Indian civilization common to both. The cultivated peoples of India professing the Hindu religion, or Hindus in the third sense, not only differ in language in different provinces of India, but in customs and dress. The Mohammedan population, on the other hand, in all parts of India, wear the same dress, affect the same customs, and speak one language—Hindustani or Urdu, a dialect which sprang up at the Mohammedan court of Delhi, and which is a highly cultivated form of Hindi intermixed with a large number of Persian and Arabic words. It is the language generally used by the British government in official business. In several provinces, however, attempts have been recently made to substitute for it the local languages, such as Sindhi and Assami, many of which have received little literary cultivation.

The returns published with reference to books published in India in 1872 unfortunately do not refer to all the provinces, but they give some idea of the relative importance of the native languages. In the North-west Provinces, out of 317 books published, 90 were in Hindustani or Urdu, 53 in Hindi, 56 in Persian, 47 in Arabic, and 33 in English. In the Madras presidency, out of 508 published, 177 were in Tamil, 115 in Telugu, 26 in Malayalim, 22 in Canarese, and 70 in English. In Bombay Presidency, out of 779 books, 214 were in Mahrati, 243 in Gugerati, and 157 in English. In Bengal, 759 native books were published, but in what languages is not stated.

In India there are rude tribes belonging to the Mongol, Dravidian, and Aryan races. The Siahposh Kaffirs and kindred tribes of Dardistan are undoubted Aryans, who know nothing of Hindu culture. The Mongols n. and e. of the Terai, in the same way, have none of the culture of Bhotan, Thibet, and China. They have caused much trouble on the Assam frontier, where several districts are excluded from the operation of regular laws, and the deputy-commissioner of Assam now holds an annual meeting of the hill-tribes. From 1854 to 1865 the Angami Nagas made 19 raids into the plains, and killed 236 people; but in the latter year a military post was occupied in their country, and the raids have ceased. The hill-tribes of the Dravidian race are also in the lowest stage of savagery. Among the most important and best known of them are the Bheels, who are found in Candeish; and the Khonds and Koles, who inhabit Orissa. The former were wont to live by plunder, and used to burst out of their jungles like tigers, committing the most frightful excesses; but in 1825, after various methods of subduing them had been unsuccessfully tried by the British government, it was resolved to tempt them into military service. A Bheel corps was raised, into which all the wilder spirits were drafted, and the result has been a very decided improvement in the habits and disposition of the rest of the people. Roads have now been made through their country, and property is quite safe. The Khonds and Koles, however, are perhaps a more interesting race, since they have preserved more completely what may be regarded as the primitive religion of Hindustan. Forced into the jungles and mountains of Central India, by the victorious advance of the Aryan race from the n.w., they have preserved (in part at least), in their almost inaccessible retreats, the grim religion that prevailed in the peninsula before Brahmanism was heard of. That religion may be briefly characterized as devil-worship. The Khonds sacrifice only to malignant deities, such as Siva the destroyer, the goddess Kali, and the God of the earth, whom they seek to propitiate by human sacrifice, principally of children, who, however, are not taken from their own

race, but kidnapped from neighboring tribes. Successful efforts have been made by the British government to suppress these practices.

To the present civilized inhabitants of India, who, although generally a mixed race of Dravidian and Aryan origin, now form many distinct nations, no general statement can apply. The acute but timid Bengali resembles little the warlike Sikh of the Punjab, or the fierce Afghan of Rohilcund; and the patient weaver of Dacca is wholly unlike the high-spirited Rajpût of Central India. The Sikh is a born soldier, who despises the Hindu, and hates the Mussulman. He cares nothing for caste, and is brave, faithful, and independent. The Mohammedans of India are degenerate followers of the prophet, and their religion is a strange mixture of the doctrines of the Koran with the idolatry of Asia. The Parsees, a mercantile and educated class, seated at Bombay and along the w. coast of India, are the descendants of the fugitive fire-worshipers of Persia (see PARSEES). Of the morality of the civilized races of India, in general, Mr. Markham says that, whatever may be said of the larger towns, the residents of villages are "singularly temperate as a rule, chaste, honest, peaceful, singularly docile, easily governed, and patient."

Two of the most striking peculiarities of the social condition of the Hindus are the institution of caste (q.v.) and the *village-system*. The latter is very simple. A village in Hindustan does not mean a collection of houses at a particular spot, but corresponds rather to what is called a township in America. It is a district embracing an area of some hundreds or thousands of acres of land, and is under the administration of native functionaries, the principal of whom is the *potail* (head-inhabitant), a kind of chief magistrate, who superintends the affairs of the community, settles disputes, attends to the police and the collection of taxes. Among the other functionaries may be mentioned the *curnum*, who keeps a register of the produce and the names of the proprietors, and draws up all deeds of sale, transfer, etc.; the Brahman, or village priest; and the schoolmaster. Besides these, every village has its astrologer, smith, carpenter, potter, barber, doctor, dancing-girl, musician, and poet, all of whom are rewarded for their labors out of the produce of the village lands. "Under this simple form of municipal government, the inhabitants of the country have lived from time immemorial. The boundaries of the village have been but seldom altered; and though the villages themselves have been sometimes injured, and even desolated by war, famine, and disease, the same name, the same limits, and even the same families, have continued for ages. The inhabitants give themselves no trouble about the breaking up and division of kingdoms; while the village remains entire, they care not to what power it is transferred, or to what sovereign it devolves; its internal economy remains unchanged; the potail is still the head-inhabitant, and still acts as the petty judge and magistrate, and collector, or renter of the village."

Religion.—Hinduism or Brahmanism is the religion of the great majority of the inhabitants of India. Mohammedanism comes next, and it appears, from the last census, that the number of persons professing this creed is much greater than had been supposed. Of the 66,000,000 forming the population of Bengal, 21,000,000 are Mohammedans. In the Punjab, 9,000,000 are Mohammedans and 6,000,000 Hindus. In Oude there are 1,000,000 of Mohammedans to 10,000,000 of Hindus. In the North-western Provinces there are 25,000,000 of Hindus to 4,000,000 of Mohammedans. In the whole of India it is believed there are nearly three times as many Hindus as Mohammedans. The Sikh religion (see SIKHS) is professed, according to the census for the Punjab, by 1,000,000 of the inhabitants. They hate alike the Hindus and the Mohammedans. Buddhism at one period prevailed very generally throughout India; it is now confined to Bhotan, Ceylon, and the Burmese frontier. Several of the forms of religion prevalent among the natives of India are treated of apart (see BUDDHISM, MOHAMMEDANISM, PARSEES, SIKHS); what we shall here specially consider is that variety of creeds which is derived from Brahmanic sources, and known as the Hindu religion, or Hinduism. The term Hinduism, however, must not be taken as restricted to those forms of the Brahmanic religion which are in existence now; we have to look upon it as comprising all the phases of this creed up to its earliest period.

We may divide Hinduism into three great periods, which, for brevity's sake, we will call the Vedic, Epic, and Purânic periods, as our knowledge of the first is derived from the sacred books called the *Veda;* of the second, from the epic poem called the *Râmâyana*, and more especially from the great epos, the *Mahâbhârata;* while the chief source of our information relative to the last period is that class of mythological works known under the name of *Purânas* and *Tantras*. It is necessary here to guard the reader against attempting to connect dates with the earlier of those periods. It has not been uncommon for writers on this subject to assign thousands of years before the Christian era as the starting-points of various phases of Hindu antiquity; others, more cautious, marked the beginnings of certain divisions of Vedic works with 1200, 1000, 800, and 600 years B.C. The truth is, that while Hindu literature itself is almost without known dates, owing either to the peculiar organization of the Hindu mind, or to the convulsions of Indian history, the present condition of Sanskrit philology does not afford the scholar the requisite resources for embarking with any chance of success in such chronological speculations. This question of Hindu chronology will be more particularly considered in the article VEDA. In the mean time, the utmost stretch of

assumption which in the actual condition of Sanskrit philology it is permitted to make is, that the latest writings of the Vedic class are not more recent than the 2d c. before Christ. A like uncertainty hangs over the period at which the two great epic poems of India were composed, although there is reason to surmise that the lower limits of that period did not reach beyond the beginning of the Christian era. The Purânic period, on the other hand, all scholars are agreed to regard as corresponding with part of our mediæval history.

If the *Rig-Veda*—the oldest of the Vedas, and probably the oldest literary document in existence—coincided with the beginning of Hindu civilization, the popular creed of the Hindus, as depicted in some of its hymns, would reveal not only the original creed of this nation, but throw a strong light on the original creed of humanity itself. Unhappily, however, the imagination, indulging in such an hypothesis, would have as little foundation to work on as that which would fix the chronological position of this Veda. The Hindus, as depicted in these hymns, are far removed from the starting-point of human society; nay, they may fairly claim to be ranked among those already civilized communities experienced in arts, defending their homes and property in organized warfare, acquainted even with many vices which only occur in an advanced condition of artificial life. See VEDA. Yet in examining the ideas expressed in the greatest number of the Rig-Veda hymns, it cannot be denied that they are neither ideas engendered by an imagination artificially influenced, nor such as have made a compromise with philosophy. The Hindu of these hymns is essentially engrossed by the might of the elements. The powers which turn his awe into pious subjection and veneration are—*Agni*, the fire of the sun and lightning; *Indra*, the bright, cloudless firmament; the *Maruts*, or winds (see MARUT); *Sûrya*, the sun (see SÛRYA); *Ushas*, the dawn (see USHAS); and various kindred manifestations of the luminous bodies, and nature in general. He invokes them, not as representatives of a superior being, before whom the human soul professes its humility; not as superior beings themselves, which may reveal to his searching mind the mysteries of creation or eternity, but because he wants their assistance against enemies—because he wishes to obtain from them rain, food, cattle, health, and other worldly goods. He complains to them of his troubles, and reminds them of the wonderful deeds they performed of yore, to coax them, as it were, into aquiescence and friendly help. "We proclaim eagerly, *Maruts*, your ancient greatness, for the sake of inducing your prompt appearance, as the indication of (the approach of) the showerer of benefits;" or: "Offer your nutritious viands to the great hero (*Indra*), who is pleased by praise, and to *Vishnu* (one of the forms of the sun), the two invincible deities who ride upon the radiant summit of the clouds as upon a well-trained steed. *Indra* and *Vishnu*, the devout worshiper glorifies the radiant approach of you two who are the granters of desires, and who bestow upon the mortal who worships you an immediately receivable (reward), through the distribution of that fire which is the scatterer (of desired blessings)." Such is the strain in which the Hindu of that period addresses his gods. He seeks them, not for his spiritual, but for his material welfare. Ethical considerations are therefore foreign to these instinctive outbursts of the pious mind. Sin and evil, indeed, are often adverted to, and the gods are praised because they destroy sinners and evil-doers; but one would err in associating with these words our notions of sin or wrong. A sinner, in these hymns, is a man who does not address praises to those elementary deities, or who does not gratify them with the oblations they receive at the hands of the believer. He is the foe, the robber, the demon—in short, the borderer infesting the territory of the "pious" man, who, in his turn, injures and kills, but, in adoring Agni, Indra, and their kin, is satisfied that he can commit no evil act. Yet we should be likewise wrong did we judge of those acts of retaliation by the standard of our own ethical laws. So far, indeed, from reflecting unfavorably on the internal condition of the Hindu community, the features of which may be gathered from these hymns, they seem, on the contrary, to bespeak the union and brotherhood which existed amongst its members; and the absence, in general, of hymns which appeal to the gods for the suppression of internal dissensions or public vices, bears, apparently, testimony to the good moral condition of the people whose wants are recorded in these songs.

It may be imagined that the worship of elementary beings like those we have mentioned was originally a simple and harmless one. By far the greatest number of the Rig-Veda hymns know of but one sort of offering made to these gods; it consists of the juice of the soma or moon-plant, which, expressed and fermented, was an exhilarating and inebriating beverage, and for this reason, probably, was deemed to invigorate the gods, and to increase their beneficial potency. It was presented to them in ladles, or sprinkled on the sacred Kusa grass. Clarified butter, too, poured on fire, is mentioned in several hymns as an oblation agreeable to the gods; and it may have belonged to this, as we hold, primitive stage of the Vedic worship.

There is a class of hymns, however, to be found in the Rig-Veda which depart already materially from the simplicity of the conceptions we are referring to. In these, which we conceive to be of another order, this instinctive utterance of feeling makes room for the language of speculation; the allegories of poetry yield to the mysticism of the reflecting mind; and the mysteries of nature becoming more keenly felt, the circle of beings which overawe the popular mind becomes enlarged. Thus, the objects by which Indra, Agni, and the other deities are propitiated, become gods themselves; soma,

especially, the moon-plant and its juice, is invoked as the bestower of all worldly boons. The animal sacrifice, the properties of which seem to be more mysterious than the offerings of soma, or of clarified butter—is added to the original rites. We will quote a few verses from the second book of the Rig-Veda, which may illustrate the essential difference between this order of hymns and those we alluded to before. It is the horse of the sacrifice which is invoked by the worshiper, and its properties are praised in the following strain:

"Thy great birth, O Horse, is to be glorified; whether first springing from the firmament or from the water, inasmuch as thou hast neighed, for thou hast the wings of the falcon and the limbs of the deer. Trita harnessed the horse which was given by Yama, Indra first mounted him, and Gandharba seized his reins. Vasus, you fabricated the horse from the sun. Thou, horse, art Yama: thou art Aditya, thou art Trita by a mysterious act: thou art associated with Soma. The sages have said there are three bindings of thee in heaven," etc.

Mystical language like this doubtless betrays the aberration of the religious instinct of a nation; but it also reveals the fact, that the pious mind of the Hindus was no longer satisfied with the adoration of the elementary or natural powers; it shows that religion endeavored to penetrate into the mysteries of creation. This longing we find, then, expressed in other hymns, which mark the beginning of the *philosophical creed of the Vedic period.* The following few verses may tend to illustrate the nature of this third class of hymns, as they occur in the oldest Veda: "I have beheld the Lord of Men," one poet sings, "with seven sons [i.e., the seven solar rays], of which delightful and benevolent (deity), who is the object of our invocation, there is an all-pervading middle brother, and a third brother [i.e., Vâyu and Agni, the younger brothers of Aditya, the sun], well fed with (oblations of) clarified butter. They yoke the seven (horses) to the one-wheeled car [i.e., the orb of the sun, or time, or a year]; one horse [i.e., the sun], named seven, bears it along: the three-axled wheel [i.e., the day with its three divisions, or the year with three seasons—hot, wet, and cold; or time—past, present, and future] is undecaying, never loosened, and in it all these regions of the universe abide. . . . Who has seen the primeval (Being) at the time of his being born? What is that endowed with substance which the unsubstantial sustains? From earth are the breath and blood, but where is the soul? Who may repair to the soul to ask this? Immature (in understanding), undiscerning in mind, I inquire of those things which are hidden, (even) from the gods, (what are) the seven threads which the sages have spread to envelop the sun in whom all abide?" Another poet sings: "Then there was no entity or non-entity; no world, or sky, or aught above it; nothing anywhere in the happiness of any one, involving or involved; nor water deep or dangerous. Death was not, nor was there immortality, nor distinction of day or night. But THAT breathed without affiation, single with her (*Swadhâ*) who is within him. Other than him, nothing existed (which) since (has) been. . . . Who knows exactly, and who shall in this world declare, whence and why this creation took place? The gods are subsequent to the production of this world, then who can know whence it proceeded, or whence this varied world arose, or whether it uphold itself or not? He who in the highest heaven is the ruler of this universe, does indeed know; but not another one can possess this knowledge."

As soon as the problem implied by passages like these was raised in the minds of the Hindus, Hinduism must have ceased to be the pure worship of the elementary powers. Henceforward, therefore, we see it either struggling to reconcile the latter with the idea of one supreme being, or to emancipate the inquiry into the principle of creation from the elementary religion recorded in the oldest portion of Vedic poetry. The first of these efforts is principally shown in that portion of the Vedas called *Brâhmana* (see VEDA), the second in the writings termed *Upanishad* (see UPANISHAD). In the *Brâhmanas*—a word of the neuter gender, and not to be confounded with the similar word in the masculine gender, denoting the first Hindu caste—the mystical allegories which now and then appear in what we have called the second class of Vedic hymns, are not only developed to a considerable extent, but gradually brought into a systematic form. Epithets given by the Rig-Veda poets to the elementary gods are spun out into legends, assuming the shape of historical narratives. The simple and primitive worship mentioned in the hymns becomes highly complex and artificial. A ponderous ritual, founded on those legends, and supported by a far more advanced condition of society, is brought into a regular system, which requires a special class of priests to be kept in a proper working order. Some of the Vedic hymns seem to belong already to the beginning of this period of the Brâhmana worship, for in the second book of the Rig-Veda several such priests are enumerated in reference to the adoration of Agni, the god of fire; but the full contingent of 16 priests, such as is required for the celebration of a great sacrifice, does not make its appearance before the composition of the Brâhmanas and later Vedas. Yet, however wild many of these legends are, however distant they become from the instinctive veneration of the elementary powers of nature, and however much this ritual betrays the gradual development of the institution of castes—unknown to the hymns of the Rig-Veda—there are still two features in them, which mark a progress of the religious mind of ancient India. While the poets of the Rig-Veda are chiefly concerned in glorifying the *visible* manifestations of the elementary gods—in the Brâhmanas, their ethical qualities are put forward for imitation and praise. Truth and

untruth, right and wrong—in the moral sense which these words imply—are not seldom emphasized in the description of the battles fought between gods and demons; and several rites themselves are described as symbolical representations of these and similar qualities of the good and evil beings, worshiped or abhorred. A second feature is the tendency, in these Brâhmanas, of determining the *rank* of the gods, and as a consequence, of giving prominence to one special god amongst the rest; whereas in the old Vedic poetry, though we may discover a predilection of the poets to bestow more praise, for instance, on Indra and Agni, than on other gods, yet we find no intention, on their part, to raise any of them to a supreme rank. Thus, in some Brâhmanas, *Indra*, the god of the firmament, is endowed with the dignity of a ruler of the gods; in others, the *sun* receives the attributes of superiority. This is no real solution of the momentous problem hinted at in such Vedic hymns as we quoted before, but it is a semblance of it. There the poet asks "whence this varied world arose"—here the priest answers that "one god is more elevated than the rest;" and he is satisfied with regulating the detail of the soma and animal sacrifice, according to the rank which he assigns to his deities.

A real answer to this great question is attempted, however, by the theologians who explained the "mysterious doctrine," held in the utmost reverence by all Hindus, and laid down in the writings known under the name of *Upanishads*. It must suffice here to state that the object of these important works is to explain, not only the process of creation, but the nature of a supreme being, and its relation to the human soul. In the Upanishads, Agni, Indra, Vâyu, and the other deities of the Vedic hymns, become symbols to assist the mind in its attempt to understand the true nature of one absolute being, and the manner in which it manifests itself in its worldly form. The human soul itself is of the same nature as this supreme or great soul: its ultimate destination is that of becoming reunited with the supreme soul, and the means of attaining that end is not the performance of sacrificial rites, but the comprehension of its own self and of the great soul. The doctrine which at a later period became the foundation of the creed of the educated—the doctrine that the supreme soul, or (the neuter) Brahman, is the only reality, and that the world has a claim to notice only in so far as it emanated from this being, is already clearly laid down in these Upanishads, though the language in which it is expressed still adapts itself to the legendary and allegorical style which characterizes the Brâhmana portion of the Vedas. *The Upanishads became thus the basis of the enlightened faith of India.* They are not a system of philosophy, but they contain all the germs whence the three great systems of Hindu philosophy arose; and like the latter, while revealing the struggle of the Hindu mind to reach the comprehension of one supreme being, they advance sufficiently far to express their belief in such a being, but at the same time acknowledge the inability of the human mind to comprehend its essence. For the different periods which must be distinguished in the composition of these works, and for the gradual development of the general ideas briefly adverted to here, we refer the reader to the article UPANISHAD.

The EPIC period of Hinduism is marked by a similar development of the same two creeds, the general features of which we have now traced in the Vedic writings. The popular creed strives to find a center round which to group its imaginary gods, whereas the philosophical creed finds its expression in the groundworks of the *Sânkhya*, *Nyâya*, and *Vedânta* systems of philosophy. In the former, we find two gods in particular who are rising to the highest rank, Vishnu and Siva; for as to Brahmâ (the masculine form of Brahman), though he was looked upon, now and then, as superior to both, he gradually disappears, and becomes merged into the philosophical Brahma (the neuter form of the same word), which is a further evolution of the great soul of the Upanishads. In the *Râmâyana*, the superiority of Vishnu is admitted without dispute; in the great epos, the *Mahâbhârata*, however, which, unlike the former epos, is the product of successive ages, there is an apparent rivalry between the claims of Vishnu and Siva to occupy the highest rank in the pantheon; but Sanskrit philology will first have to unravel the chronological position of the various portions of this work, to lay bare its groundwork, and to show the gradual additions it received, before it will be able to determine the successive formation of the legends which are the basis of classical Hindu mythology. Yet so much seems to be clear even already that there is a predilection during this epic period for the supremacy of Vishnu; and that the policy of incorporating rather than combating antagonistic creeds, led more to a quiet admission than to a warm support of Siva's claims to the highest rank. For the character of these gods, for the relation in which the conception of these beings stands to that of the Vedic time, for the new ideas which they impersonate at the epic period, and for the group of mythological beings connected with both of them, we refer the reader to the respective articles. We will point, however, to one remarkable myth, as it will illustrate the altered position of the gods during the epic period. In the Vedic hymns, the immortality of the gods is never matter of doubt; most of the elementary beings are invoked and described as everlasting, as liable neither to decay nor death. The offerings they receive may add to their comfort and strength; they may invigorate them, but it is nowhere stated that they are indispensable for their existence. It is, on the contrary, the pious sacrificer himself who, through his offerings, secures to himself long life, and, as it is sometimes hyperbolically called, immortality. And the same notion prevails throughout the oldest Brâhmanas. It is only in the latest work of this class, the *Satapatha-Brâhmana*, and

more especially in the epic poems, that we find the inferior gods as mortal in the beginning, and as becoming immortal through exterior agency. In the *Satapatha-Brâhmana*, the juice of the soma plant, offered by the worshiper, or at another time clarified butter, or even animal sacrifices, impart to them this immortality. At the epic period, Vishnu teaches them how to obtain the *amrita*, or beverage of immortality, without which they would go to destruction; and this epic *amrita* itself is merely a compound, increased by imagination, of the various substances which in the Vedic writings are called or likened to *amrita*, i.e., a "substance that frees from death." It is obvious, therefore, that gods like these could not strike root in the religious mind of the nation. We must look upon them more as the gods of poetry than of real life; nor do we find that they enjoyed any of the worship which was allotted to the two principal gods, Vishnu and Siva.

The philosophical creed of this period adds little to the fundamental notions contained in the Upanishads; but it frees itself from the legendary dross which still imparts to those works a deep tinge of mysticism. On the other hand, it conceives and develops the notion that the union of the individual soul with the supreme spirit may be aided by penances, such as peculiar modes of breathing, particular postures, protracted fasting, and the like; in short, by those practices which are systematized by the Yoga doctrine. The most remarkable epic work which inculcates this doctrine is the celebrated poem *Bhagavadgîtâ*, which has been wrongly considered by European writers as a pure Sânkhya work, whereas *Sankara*, the great Hindu theologian, who commented on it, and other native commentators after him, have proved that it is founded on the Yoga belief. The doctrine of the reunion of the individual soul with the supreme soul, was necessarily founded on the assumption that the former must have become free from all guilt affecting its purity before it can be remerged into the source whence it proceeded; and since one human life is apparently too short for enabling the soul to attain its accomplishment, the Hindu mind concluded that the soul, after the death of its temporary owner, had to be born again, in order to complete the work it had left undone in its previous existence, and that it must submit to the same fate until its task is fulfilled. This is the doctrine of *metempsychosis*, which, in the absence of a belief in grace, is a logical consequence of a system which holds the human soul to be of the same nature as that of an absolute God. The beginning of this doctrine may be discovered in some of the oldest Upanishads, but its fantastical development belongs to the epic time, where it pervades the legends, and affects the social life of the nation. See METEMPSYCHOSIS.

The PURÂNIC period of Hinduism is the period of its decline, so far as the popular creed is concerned. Its pantheon is nominally the same as that of the epic period. Brahmâ, Vishnu, and Siva remain still at the head of its imaginary gods; but whereas the epic time is generally characterized by a friendly harmony between the higher occupants of the divine spheres, the Purânic period shows discord and destruction of the original ideas whence the epic gods arose. Brahmâ withdraws, in general, from the popular adoration, and leaves Vishnu and Siva to fight their battles in the minds of their worshipers for the highest rank. The elementary principle which originally inhered in these deities is thus completely lost sight of by the followers of the Purânas. The legends of the epic poems relating to these gods become amplified and distorted, according to the sectarian tendencies of the masses; and the divine element which still distinguishes these gods in the Râmâyana and Mahâbhârata, is now more and more mixed up with worldly concerns and intersected with historical events, disfigured in their turn to suit individual interests. Of the ideas implied by the Vedic rites, scarcely a trace is visible in the Purânas and Tantras, which are the text-books of this creed. In short, the unbridled imagination which pervades these works is neither pleasing from a poetical, nor elevating from a philosophical point of view. Some Purânas, it is true —for instance, the *Bhâgavata*—make in some sense an exception to this aberration of original Hinduism; but they are a compromise between the popular and the Vedânta creed, which henceforward remains the creed of the educated and intelligent. They do not affect the worship of the masses as practiced by the various sects; and this worship itself, whether harmless, as with the worshipers of Vishnu, or offensive, as with the adorers of Siva and his wife Durgâ, is but an empty ceremonial, which, here and there, may remind one of the symbolical-worship of the Vedic Hindu, but, as a whole, has no connection whatever with the Vedic scriptures, on which it affects to rest. It is this creed which, with further deteriorations, caused by the lapse of centuries, is still the main religion of the masses in India. The opinion these entertain, that it is countenanced by the ritual, as well as by the theological portion of the Vedas, is the redeeming feature of their belief; for, as nothing is easier than to disabuse their mind on this score, by reviving the study of their ancient and sacred language, and by enabling them to read again their oldest and most sacred books, it may be hoped that a proper education of the people in this respect, by learned and enlightened natives, will remove many of the existing errors, which, if they continued, must inevitably lead to a further, and, ultimately, total degeneration of the Hindu race.

The philosophical creed of this period, and the creed which is still preserved by the educated classes, is that derived from the tenets of the Vedânta philosophy. It is based on the belief of one supreme being, which imagination and speculation endeavor to invest with all the perfections conceivable by the human mind, but the true nature of

which is, nevertheless, declared to be beyond the reach of thought, and which, on this ground, is defined as not possessing any of the qualities by which the human mind is able to comprehend intellectual or material entity. See VEDÂNTA.

Hindu Sects.—This designation applies to the sects which arose during the third period of Hinduism. They suppose that their worship is countenanced by the Vedas; but its real origin is derived from the *Purânas* and *Tantras*. See these articles. There are three chief divisions of these sects—the adorers of Vishnu, of Siva, and of the wives or female energies of these gods. See VAISHNAVAS, SAIVAS, and SÂKTAS. Besides these great sects, there are some of limited extent and total insignificance, such as the worshipers of *Agni*, the god of fire; of *Sûrya*, the sun-god; of *Ganesa*, the god of wisdom, and the obviator of impediments. For a detailed account of these and similar sects, see the first volume of the *Works of the late H. H. Wilson*, containing a sketch of the religious sects of the Hindus.

For an account of the various divisions of India, see articles on the various provinces referred to in the preceding article. See also INDIA, BRITISH; INDIA, NATIVE STATES OF; INDIA, FRENCH; INDIA, PORTUGUESE.

For an account of the philosophy, literature, architecture, etc., of India, see SANSKRIT LITERATURE MÎMÂNSÂ, NYÂYA, SÂNKHYA, VEDÂNTA. For the history of India, see following article.

INDIA, BRITISH, is the name given to those parts of Hither and Further India placed under the administration of the viceroy or governor-general of India. It does not include Ceylon, which, although a British possession, has its government entirely separate from that of Hindustan; but it extends along the eastern coast of the bay of Bengal to 10° s. lat., and thus includes part of Further India or Indo-China.

The following are the returns of the census of 1868–72, subsequently revised and corrected:

Territories and Provinces under the Administration of	Area in English Sq. Miles.	Population.	Average Pop. per Sq. Mile.
Governor-general of India—			
Ajmere and Mairwara	2,711	396,889	146
Coorg	2,000	163,312	84
Berar	17,631	2,226,496	126
Mysore	29,325	5,055,412	172
Governor of Madras	137,971	31,672,613	230
" Bombay	124,462	16,349,206	131
Lieutenant-governor of Bengal	157,989	60,502,897	383
" North-west Provinces	81,403	30,781,204	378
" Punjab	104,975	17,611,498	168
Chief Commissioner of Oude	23,992	11,220,232	468
" Assam	53,856	4,132,019	99
" Central Provinces	84,963	8,201,519	97
" British Burmah	88,556	2,747,148	31
Total	909,834	191,065,445	210

Government.—By an act of parliament, which received the royal assent Aug. 2, 1858, queen Victoria was declared sovereign of India, and various regulations were enacted for the better government of the country. In 1877, by act of parliament, the queen formally assumed the title empress of India. The home-government of India is vested in a secretary of state, who is a member of the English cabinet. He is assisted by an under-secretary and a council of fifteen members. The Indian executive government is administered by the viceroy or governor-general appointed by the crown, and acting under the control of the secretary of state for India. The viceroy is appointed by the crown for a term of six years, and is assisted by a council of five ordinary members, three appointed by the secretary of state, two by her majesty's warrant. Each of them has charge of a department of the executive. The commander-in-chief may be constituted an extraordinary member of the council. The legislative council is composed of the members of the executive, together with twelve members, one half of whom must be unconnected with the public service. They are nominated for two years by the viceroy. British India is now divided into the provinces mentioned in the preceding table. It was formerly divided into the three presidencies of Bengal, Madras, and Bombay; and in ordinary language, and even in official documents, the name of presidency is still given to the provinces of Madras and Bombay. As regards military matters, the old threefold division may be said to subsist, but it must be kept in mind that British India is now divided into the four territories under the governor-general, and the nine provinces, enumerated in the preceding table, and that each has its own civil government, and is independent of the others. The two governments of Madras and Bombay are under the rule of governors apppointed by the crown, and assisted by executive and legislative cou cils. They communicate only with regard to important matters with the home government through the governor-general. As regards affairs of minor importance, they correspond directly with the secretary of state for India. The Lower Provinces of Bengal, the North-west Provinces, and the Punjab are administered by lieutenant-governors appointed by the governor-general, subject to the approbation of the secretary of state for India. In Bengal, the

lieutenant-governor is assisted by a legislative council. Oude, Assam, the Central Provinces, and British Burmah are governed by chief-commissioners appointed by the Indian government. Ajmere was separated from the government of the North-west Provinces in 1871, and placed under the direct control of the governor-general. Berar, also known under the name of the assigned districts of Hyderabad, Mysore, and Coorg, are administered by commissioners appointed by the governor-general. All the governments of India are split into provinces, over each of which a commissioner is placed, and these are in turn divided into districts under a judge and collector. The provinces are distinguished into regulation and non-regulation provinces. In the former the revenue is collected and justice is administered according to fixed methods. In the latter, power is reserved by legislative enactment to modify these as occasion requires. Resident political agents are appointed by the British government at the courts of the native princes. The *Covenanted Civil Service* is composed of Europeans who conduct the general administration in the Indian provinces. Since 1854 the members have been recruited from the successful candidates at competitive examinations instituted for the purpose, held in London. The *Uncovenanted Civil Service*, appointments to which are made by the authorities in India, is composed of Europeans, Eurasians (the class sprung from native mothers by European fathers), and natives. Municipalities in India were first created for the three presidency towns, and it was not till 1850, 1856, and 1868, that acts were passed under which a large number of Indian towns have obtained municipal institutions, which are gradually diffusing the habit of self-government over the whole country.

Military Force.—The Indian military service, like the civil service, underwent a thorough reorganization, consequent on the great mutiny, and the transfer of the government of the country from the East India company to the crown. In 1878 the established military force of British India numbered 190,175, including officers; of whom 123,682 were natives, and 60,227 English (exclusive of officers). India is divided into three military divisions, which, although named after the three old presidencies of Bombay, Madras, and Bengal, and perpetuating their names, have not exactly the same limits. Of the native troops, 47,000 belonged to the Bengal army, 27,000 to the Madras army, and 24,000 to the Bombay army. The British forces are chiefly stationed in the Punjab, and along the valley of the Ganges. In 1872 there were 37,000 English soldiers in these provinces, of whom 12,000 were in the Punjab, 10,400 were in the Bombay presidency, and 12,200 in that of Madras.

The Police in British India include a force of 190,000 constables or regular policemen, and the village watchmen who aid them. The minimum age of admission is 17, the maximum 21. Each district has a jail and a police superintendent; and the districts are grouped, for police purposes, into circles under deputy-inspectors-general, while the whole police force in each province is under an inspector-general. The constabulary is a purely civil force, subject in all respects, except internal discipline, to the civil authorities.

Administration of Civil Justice.—In 1861, by an act of parliament, high courts of judicature were established at each presidency and in the North-west Provinces, under the control of a chief-justice, and as many other judges, not exceeding fifteen, as her majesty may appoint. In 1871–72, there were 1,088,153 civil suits in India, and there can be no doubt that the machinery for litigation supplied by the courts is much employed. Sir G. Campbell, however, fears that the tendency to uphold the bare doctrines of law—the literal fulfillment of contracts alleged to have been entered into by ignorant and improvident people—leads to great hardship in cases which affect poor men and benefit the rich and litigious. The civil procedure code of India offers facilities for litigation which are apt to be abused. Sir George Campbell, in illustration of the views entertained of legal proceedings by some classes of Indian litigants, gives the following account of a litigation between the members of a family originally belonging to one of the hill-tribes. One of the parties, after litigating through all the courts of India, got a decree in the highest court. But there was an appeal to the privy council, and the suitor's funds were exhausted. So they caught an old man, carried him to the top of a hill, and sacrificed him to propitiate the gods who rule the decisions of the privy council. The civil procedure code worked such mischief among the Sontals, that the people were exasperated, and had to be removed from the operation of laws applicable generally in Bengal.

Revenue, Expenditure, etc.—The annexed table shows the gross amount of the public revenue and expenditure of British India, with the surplus or deficiency of revenue in each of the under-mentioned years:

Years ended.	Gross Revenue.	Total Expenditure.		Gross Expenditure.		Surplus (+) or Deficiency (−) of Revenue.	
		In India.	In England.	Exclusive of Public Works Extraordinary.	Including Public Works Extraordinary.	Exclusive of Public Works Extraordinary.	Including Public Works Extraordinary.
1869....	49,262,691	43,225,587	10,181,747	52,036,721	53,407,334	−2,774,030	−4,144,643
1870 ...	50,901,081	42,791,013	10,591,013	50,782,412	53,382,026	+ 118,669	−2,480,945
1871 ...	51,413,686	41,015,502	10,083,004	49,930,696	51,098,506	+1,482,990	+ 315,180
1872....	50,110,215	40,486,818	8,127,694	46,986,038	48,614,512	+3,124,177	+1,495,703

The gross amount of the public revenue and expenditure in each province in British India, exclusive of receipts and expenditure in England, for the year ending Mar. 31, 1875, is shown below:

	Revenue.	Expenditure.
India under the governor-general	£2,568,299	£13,447,250
Bengal	15,087,294	8,057,769
North-west Provinces	5,879,317	2,202,025
Oude	1,587,004	575,648
Punjab	3,747,682	1,747,472
Central Provinces	956,212	693,883
British Burmah	1,488,148	771,218
Assam	552,001	361,290
Madras	8,873,826	5,897,554
Bombay (including Sinde)	9,986,805	7,006,474
Totals	£50,226,588	£40,760,583

The revenues and expenditure of the Eastern settlements, and of Hyderabad assigned districts, or the Berars, are separated from the revenues and expenditure of British India, and not included in the above statement. The total revenue of British India for 1878–79 was estimated at £63,195,000; the expenditure at £61,039,000. The chief items of the revenue are much in the same proportion year by year. In 1875 they were: land revenue, £21,037,912; opium, £8,324,879; salt, £6,150,662; stamps, £2,758,042; customs, £2,678,479; excise on spirits and drugs, £2,346,143. The land tax alone produces nearly the half of the whole revenue. In India the government has always been considered the owner of the soil, and the actual cultivators pay a rent or tax, in collecting which different systems have hitherto been followed in different parts of the country, known as the *Zemindari Settlement*, *Ryotwar*, and *Mouzawar* or *Village Settlement*. The latter is the oldest and the simplest system. Each village under this arrangement was regarded as a separate municipality, and each was assessed by the government at a particular sum, for the due payment of which the headman of the village was considered responsible. The individual distribution of the burden of taxation rested with the village authorities, and government, provided it received its regular dues through the *potail*, interfered no further. The origin of the Zemindari and Ryotwar settlements requires some explanation. When the English first entered upon the administration of the country, they found that the practice of native sovereigns, their predecessors, had been to farm out the land revenues of the country to the nobles of the court, or to wealthy bankers, who annually paid a fixed amount into the royal treasury, and collected the government dues on their own behalf, from the actual cultivators of the soil. These farmers of the revenue were termed Zemindars. The question for the English rulers arose, whether or not they were to consider these men as proprietors. In Bengal and Bahar they were so recognized, and confirmed in their position, the government holding them responsible for the payment of the dues on their estates, and regarding the cultivators on the farms as their tenants. This was lord Cornwallis's Zemindari settlement. In Madras and Bombay, the opposite course was pursued. Claims of the middlemen, or farmers of the revenue, to enjoy any proprietary rights were totally ignored; and under sir Thomas Monro, the ryotwar system was introduced, by which government makes a separate settlement with each individual cultivator or *ryot*, who is recognized as the virtual proprietor of the land, or tenant direct under government, so long as he pays the land-tax annually charged on his estate or farm. In 1871, under the administration of lord Mayo, there was created a new department of revenue, agriculture, and commerce. It has charge of all questions relating to land revenue and settlements, works of agricultural improvement, silks and fibers, forests, commerce, trade, and the industrial arts. It has also under its charge the collection of statistics, placed under another new department, the statistical survey of India, of which the director-general is Dr. Hunter. His book on Orissa (see below) was the first installment of the work done. A series of leading questions has been issued by the director-general, showing exactly what information is required from residents in the different districts. A connected account of each district will be prepared from the returns, and these will be in turn condensed by the director-general into an imperial statistical account of India. "This survey," says Mr. Markham, "forms an epoch in statistical enterprises, and its practical results will be most important."

Currency.—In British India, accounts are kept in rupees, annas, and pie—16 annas going to the rupee, and 12 pie to the anna. The coins are rupees (value 2s. sterling), and half and quarter and half-quarter rupees, in silver; and in copper $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{8}$, $\frac{1}{16}$, $\frac{1}{32}$, of an anna. The currency of India, however, is chiefly silver, of which a large amount is coined annually. The coinage bears the impress of queen Victoria as empress of India, in the native costume. In 1861 an act was passed by the government of India providing for the issue of a paper currency by means of promissory notes. The amount of notes in circulation in 1877 was £11,641,654.

The public debt of India in India and England in 1872 amounted to £112,314,760, on which the interest paid was £533,329. In 1877 the total amount of the debt was

£127,320,159, of which £71,923,126 had been taken up in India, and £55,397,033 in England.

Commerce.—In 1875–76, 6,259 vessels, of 2,629,923 tons, entered Indian ports in the foreign trade; and 6,201, of 799,063 tons, cleared. The great bulk of the export and import trade of India is with Great Britain and Ireland; the following table shows the Indian imports from the United Kingdom, and its exports thither.

Year ended March 31.	Total Imports.	Total Exports.
1873	£36,431,210	£56,540,042
1874	39,628,562	56,940,073
1875	44,363,134	57,984,539
1876	44,188,062	60,291,731
1877	48,876,751	65,043,789

The total value of the merchandise imported into British India in 1872 was £31,083,747; of treasure, £11,573,813. The chief items were: coal and coke, £514,794; cotton manufactures, £17,484,887; metals of all kinds, manufactured and unmanufactured, £2,390,775; salt, £913,975; raw silk, £651,595; silk manufactures, £480,948; spirits, £560,485; sugar and saccharine matter, £709,779. The total value of the exports in 1872 was as follows: Indian produce or manufactures, £61,697,225; foreign merchandise, £1,488,622; treasure, £1,476,093. The chief exports in the same year were the following: Coffee, £1,380,410; cotton wool, £21,272,430; cotton, manufactures of, £1,191,683; dyes of all kinds, £3,956,869; grains and pulse, £4,865,748; hides and skins, £2,515,860; jute and manufacture of jute, £4,299,767; opium, £13,365,228; seeds, £2,728,127; silk, £1,130,706; tea, £1,482,186; wool, £906,698. In 1875–76, the value (including treasure) of the total imports was £44,188,062; of exports, £60,291,731. The greater part of the trade of India is carried on with Great Britain; but there is also an extensive commerce with Ceylon, the Straits settlements, China, Australia, the Persian gulf, the Red sea, and several of the European states.

Roads and Railways.—Since 1836 great trunk-roads have been constructed in various parts of India. The most remarkable is that from Calcutta to Peshawer, 1400 m. long. The importance of these great works has now diminished, owing to the extension of a great railway system in India. The chief railways now open are the East Indian, from Calcutta to Delhi; the Indian Peninsula, which forms a branch to Bombay; the Delhi, Punjab, and Sinde, which will ultimately connect the system with the mouth of the Indus; the Bombay and Baroda, which runs n. from Bombay; the Madras railway, running s.e. to Madras, and thence s.w. to Beypûr on the Coromandel coast. Up to March, 1876, £93,720,794 had been expended by the guaranteed railway companies, and £8,000,000 were required to complete their lines. The net receipts in 1875 were £3,647,868, including £71,354 from the state lines. If we estimate the capital at £97,000,000, this represents an average return of £3, 15s. per cent upon the five per cent guaranteed capital, and a net loss to the government of £1,242,107. As the railways, however, are now almost completed, it is expected that their financial position will soon improve. In 1876–77 the net loss to government was only £588,467. In 1877 there were in all 6,948 m. of railway open in India, and near 3,000 more in course of construction. Nearly 17,000 m. of telegraphs connect all the important cities of British India, this Indian system being connected by three lines with England.

Irrigation Works and Canals.—We have already referred to the importance of irrigation in India, and the great attention given to the subject within late years. Our space will not permit us even to enumerate the great works recently undertaken in the basins of the Indus, Ganges, Mahanaddy, and Tapti, and in other parts of India, to supply water to the rich but parched soil, and thus extend the area of cultivation. Several of the canals are adapted for navigation as well as irrigation—and when works now in progress in Sirhind have been completed, there will be navigable communication from the Ganges to the Sutlej, and down the Indus to Kurachee. To give the greatest possible efficiency to the action of the government in relation to the extension of canals, an inspector-general of irrigation works has been appointed, with irrigation secretaries in the various provinces.

Disease in India.—The climate and sanitary condition of India give rise to pestilences which at intervals carry desolation over the country, whilst disease in its worst form is never absent. Hospitals, richly endowed and admirably regulated, supported as well by government as by private munificence, exist in all the large towns; and great efforts are constantly made to bring the benefits of medical skill and knowledge within reach of the poorer classes. In all parts of the country dispensaries have been opened, where medicines are given out, and patients advised. Much of the disease of India is due to bad water and bad drainage; and where a new water-supply has been introduced, and drains have been made, as in Calcutta, the improvement in the health of the inhabitants has been marked. Nearly 2,000,000 of persons were vaccinated in India in 1872. Mortality is fearfully aggravated by the passion of the people for pilgrimages. All ages and sexes traverse vast areas, and die by hundreds on the route. The Mohammedan pilgrims go in numbers to Mecca, Kerbela, and Jerusalem; and a large proportion never return.

Emigration and Colonization.—From the table at the head of this article, it appears that the population of British India is very unequally distributed. While Bengal resem-

bles a city in the density of its population, the adjoining provinces of Assam and Burmah, although no less fertile, have a very small number of inhabitants. The recurrence of famines in this over-peopled district shows the importance of encouraging emigration. The tea-planters are now attracting large crowds into Assam and other districts. In 1871 the number despatched was 7,022 against 4,863 in 1870, and the number is increasing. In Burmah there were 97,679 coolie immigrants in 1871–72. The distant emigration from India has become very important in recent years, and to regulate it the Indian emigration act (vii. of 1871) was passed, consolidating all previous laws for the protection of the emigrant coolies. One condition with respect to emigration from India to the British colonies is that there shall be 40 women to every 100 men. In 1871–72 the number of emigrants who left Calcutta for the West Indies was 8,231, and the condition as to the proportion of the sexes was fully complied with. In the same year 3,383 returned to Calcutta. As a rule, the Indian emigrants improve their condition by service in the West Indies. It is thought that, except to a few limited districts, colonization from England must ever be impracticable in India on account of the unfavorable character of the climate; for the European race settled in the country rapidly degenerates, and in a few generations becomes effete, and bodily and mentally enervated. A constant stream of British capital, however, and fresh directing energies in its application, is the great want, and what would secure, as nothing else can, the development of its unlimited resources. Indigo and sugar factories, and coffee and tea plantations, have been the principal undertakings in which independent British capital and energy have been hitherto embarked, and the results have been most satisfactory.

Christianity in India.—India was one of the earliest fields of Christian missions. Tradition assigns it as the scene of the apostle Thomas's labors and martyrdom. Whether this was the case or not, we find a Syrian church planted in Malabar in southern India, which undoubtedly had a very early origin. The Jesuit missionaries, from the middle of the 16th c. onwards, had a large success in India. See XAVIER, FRANCIS. The Catholic missions now confine their attention to their Christian converts. They are divided into two branches—the Portuguese or Goa branch, and the Jesuit mission. The number of the former in Bombay is not known; they number elsewhere 48,000. The Jesuit converts exceed half a million in Madras, Pondicherry, and Travancore. The earliest Protestant missionaries in India came from Holland and Denmark. With the latter mission the eminent Schwartz was connected. England's first missionary effort was put forward by the society for the propagation of the Gospel, and the Christian knowledge society, which commenced in the beginning of the 18th c., by aiding the Danish mission already established in southern India. Subsequently, the East India company adopted the policy of excluding missionaries altogether from their territories; but since the beginning of this century, when these restrictions were withdrawn, a great work has been entered on, in which all denominations are represented. In Bengal 16,000 ryots profess Protestantism. In Chota Nagpore, within the last 20 years, German missionaries have converted 20,000 Kols. In Oude and Rohilcund there are 2,000 converts. In southern India the numbers are much greater. The entire number of Indian Protestants in India in 1852 was 128,000; in 1862, 213,182; and in 1872, 318,363. Mr. Markham, who gives these figures in his report for 1873, speaking of the Protestant missions, says: "The government of India cannot but acknowledge the obligations under which it is laid by these 600 missionaries, whose blameless example and self-denying labors are infusing new vigor into the stereotyped life of the great population placed under English rule, and are preparing them to be in every way better men and better citizens of the great empire in which they dwell." In the proclamation to the princes, chiefs, and people of India, read in the principal cities, on Nov. 1, 1858, it was declared "that none shall be in anywise favored, none molested or disquieted, by reason of their religious faith and observances, but that all shall alike enjoy the equal and impartial protection of the law." The fullest toleration in matters of faith is enjoyed throughout British India. Fanaticism only, as when it seeks to enforce the burning of widows or suttee (q.v.), or offers human beings in sacrifice, is curbed by the ruling power. There is no exclusively endowed state-church, but government continues to pay the state grants made to Hindu temples and to Mohammedan mosques. Clergymen of the church of England, the church of Scotland, and the Roman Catholic church, are retained on the government establishment as civil or military chaplains. There are church of England bishops at Calcutta, Madras, and Bombay.

Education.—The education of the people of India is based on the system set forth in a dispatch of sir Charles Wood, dated July 19, 1854. The main principle of the dispatch was that European knowledge should be diffused through the languages understood by the great mass of the people; but that the teaching of English should always be combined with careful attention to the study of the vernacular languages. With regard to the wealthier classes, it was declared that the time had arrived for the establishment of universities in India, conferring degrees, and based on the model of the university of London. They were not to be places of education, but to test the value of education obtained elsewhere, and to confer degrees in arts, law, medicine, and civil engineering. Such universities have accordingly been established in Calcutta, Madras, and Bombay; and since 1859 government schools have been opened for the instruction of all classes of the Indian people. In each province there is now a director of public instruction,

assisted by school inspectors, one of whom has under his care one circle or subdivision of the province. Normal schools for the training of teachers have also been established, and attempts are being made to spread female education. In 1874–75 there were 53,764 government and private schools and colleges, giving instruction to 1,668,026 pupils, the gross expenditure on government schools from imperial and other sources being upwards of £1,000,000. In the North-west Provinces the total number of pupils under instruction is about 220,000. There are 250 boys in every 3,000 people, and of these 16 are at government schools, 14 at vernacular schools, and 2 learn English. In the same 3,000 people there are 200 girls, and 1 is at school. In 1875–6, 838 candidates passed the entrance examination at the university of Calcutta, 662 at Madras, and 431 at Bombay. The postal statistics partly illustrate native progress. The number of letters and newspapers carried by the post more than doubled in the ten years 1867–76. The total number of letters, etc., sent through the post-offices of British India in 1875–6 was 119,470,921.

Administrative Divisions.—The *Lower Provinces of Bengal*, under their lieutenant-governor. Bengal in this sense includes the provinces of Bengal, Bahar, Chota Nagpore, and Orissa. Calcutta is the seat of government. *Assam* was detached from Bengal, and made a separate government under its own chief commissioner, in 1874. For sanitary reasons the seat of government is not now at Gowhatty, but at Debrugurh. The *North-west Provinces*, under their lieutenant-governor, formerly under the same administration as the Lower Provinces of Bengal, constitute a distinct government, the capital being Allahabad. *Oude* (or *Audh*) is another local government, its head being styled chief commissioner. The seat of government is Lucknow. The *Punjab* is administered by a lieutenant-governor; its capital is Lahore. The *Central Provinces* became a separate chief commissionership in 1861; Nagpore is the chief town and seat of government. In *British Burmah*, the three provinces of Aracan, Pegu, and Tenasserim form the administration of a chief commissioner. The territories *immediately under the administration of the governor-general* are Ajmere and Mairwara, Coorg, Berar, and Mysore. Most of the preceding administrations lie within the limits of what used to be known as the presidency of Bengal. The other two "presidencies" have not much changed their areas. *Madras*, with its capital of the same name, has an official head called governor. *Bombay*, named after the seat of government, has also a "governor." It should be added that as the threefold division into presidencies is maintained for military purposes, the army of Bengal is responsible for the territory not included in Madras or Bombay, save that Mysore is garrisoned by the Madras army.

History.—The oldest history of India is entirely legendary; it is shrouded in mythical narratives, which, though of the highest interest from a religious and archæological point of view, do not enlighten us as to the dates of the personages concerned, nor as to the *reality* of the facts which they record. Thus, the solar and lunar dynasties spoken of in the epic poems, the *Rámáyana* and *Mahábhárata*, and in the *Puránas*, as well as other dynasties, like that of Pradyota, S'isunâga, and others mentioned in the *Puránas*, are for the present, at least, beyond the reach of history, in the sense in which we use this word. The first reliable date to be met with in ancient Hindu history is that of *Chandragupta;* for he is the king whom the Greek historians call *Sandrocottus;* and as he was the ally of Seleucus, we may safely conclude that he reigned about 300 B.C. He belonged to the Manrya dynasty, which contains another distinguished name, that of the king *Asôka*, who plays a prominent part in Buddhist history, and probably reigned from 263 to 226 B.C.; but since the history of this and other dynasties which reigned in different parts of India up to the time of the Mohammedan conquest concerns more the special student of Hindu antiquity and Indian history than the general reader, we must content ourselves here with referring those who take an interest in it to the admirable work of prof. Christian Lassen, the *Indische Alterthumskunde*, where they will not only find the richest material collected in any one book hitherto devoted to this subject, but also learn to appreciate the difficulties which beset the questions of ancient Hindu history and chronology.

From the Mohammedan Conquest (1001) *to the close of Viscount Canning's Administration* (1862).—*House of Ghizni* (1001–1167). The sultan Mahmûd, sovereign of the small state of Ghizni (q.v.), was the first conqueror who permanently established the Mohammedan power in India. In 1186 the house of Ghizni became extinct, and the Hindu princes fell one by one before a succession of Mohammedan dynasties, whose names and dates are as follows: *Slave kings of Delhi* (1206–1288).—One of these sovereigns, Altmish, who ascended the throne in 1211, added the greater part of Hindustan proper to his dominions, and in his reign the Mongol Genghis Khan devastated the north-eastern parts of India. In Balin's reign (about 1284) the Mongols made a second irruption into Hindustan, but were totally defeated by the monarch's eldest son, the heroic Mohammed, who fell in the action. The *Khiljis and House of Toghlak* (1288–1412).—In 1290 the Mongols made their third and last great irruption into Hindustan, but were almost annihilated by Zafir Khan, whose name became so proverbial among the Mongols, that when their horses started, they would ask them if they saw the ghost of Zafir Khan. In 1397, during the reign of the last of the Toghlak kings, the Tartar Timur, or Tamerlane, sacked Delhi, and proclaimed himself emperor of India. *The Syuds* (1412–1450). *The House of Lodi* (1450–1526). To the kings of this dynasty succeeded the *Great*

Moguls or House of Timur (1526–1707). Baber, who had for 22 years been sovereign of Cabul, invaded India for the fifth time towards the end of the year 1525 (see BABER), and after doing battle with sultan Ibrahim on the plain of Paniput, April, 1526, entered Delhi in triumph, and established himself as emperor of the Mohammedan dominions in India, in right of his ancestor Timur. He died in 1530, and was succeeded by his son Humayun. The celebrated Akbar (q.v.), son of Humayun, became emperor in 1556, and reigned for nearly 25 years. His son ascended the throne in 1605, and his grandson, Shah Jehan, in 1627. In 1658 Shah Jehan was imprisoned by his son, the famous Aurungzebe (q.v.), who usurped the imperial power. This remarkable man raised the Mogul empire to the highest pitch of greatness and splendor, and was the ablest and most powerful, as well as the most ambitious and bigoted, of his race. The death of Aurungzebe took place in 1707, and the decay of the empire, which had begun a few years before then, proceeded rapidly. "A succession of nominal sovereigns, sunk in indolence and debauchery, sauntered away life in secluded palaces." Viceroys of the Great Mogul formed their provinces into independent states; whilst Hindu and Mohammedan adventurers carved out kingdoms with the sword. The dismemberment of the Mogul empire opened a wide field for ambition and enterprise to the nations of Europe. The Venetians, the Genoese, the Portuguese, and the Dutch had by turns traded with India; and in 1602 the English appeared on the scene. See EAST INDIA COMPANY.

In 1653 Madras was raised into a presidency, and in 1668 the island of Bombay—which was the dowry of Charles II.'s queen, the Infanta Catherine of Portugal—was transferred by the crown to the company. The invasion of the Persian, Nadir Shah, in 1738, who sacked Delhi, slaughtered its inhabitants, and carried away the peacock throne, and vast treasure, hastened the fall of the Mogul empire.

1745–1761.—Great jealousy existed between the English and French, who had also established themselves in India. On the declaration of war between England and France, hostilities commenced in the Madras presidency, nor were they terminated by the peace of Aix-la-Chapelle, in 1748. The struggle in the Carnatic was continued with ardor, under pretext of supporting the claims of rival native princes to sovereignty. Clive (q.v.), the first and most famous name on that great muster-roll of British soldiers and statesmen who have thrown such luster on the British occupation of India, laid the foundation of his country's supremacy in the east. His memorable defense of Arcot in 1751, and his subsequent victories, broke the spell of French invincibility. The next memorable event was the siege and capture of Calcutta, on June 20, 1756, by Suraja Dowlah, grandson of Ali Verdi Khan, and governor or subahdar of Bengal. The prisoners, 146 in number, were confined in the small garrison prison or Black Hole, of whom only 23 survived till the morning. Clive quickly took command of an expedition fitted out at Madras, recovered Calcutta (1757), and, assisted by admiral Watson, prosecuted the war with his usual vigor, till after a hollow peace and a renewal of hostilities, Suraja Dowlah was completely defeated by Clive in the memorable battle of Plassey, June 23, 1757. Meer Jaffir, Suraja Dowlah's commander-in-chief, was placed on the musnud by the English, who from this time ruled Bengal as well as Bahar and Orissa.

Political Progress of East India Company (1764–1773).—After the battle of Buxar, fought in 1764 with Sujah Dowlah, the usurping vizier of Oude, the Mogul emperor, Shah Alum, who had previously been in the power of the defeated Sujah Dowlah, claimed the protection of the British. He confirmed the company in their possessions, and granted them the collectorate or perpetual *dewannee* of Bengal, Bahar, and Orissa, on condition of receiving the sum of £260,000 per annum. During the subsequent financial difficulties of the company, they repudiated this and other conditions which they had guaranteed to Shah Alum; and the cost to the company of maintaining their authority and standing army prevented them from undertaking public works and developing the resources of the country. The regulating act was passed in 1773, and a governor-general was appointed. In 1765 Clive purged the Indian government of oppression, extortion, and corruption, and from that, his last visit, dates the purity of the administration of our eastern empire.

Administration of Warren Hastings (1773–85).—Warren Hastings was the first governor-general of India. A new power, the supreme court of judicature, appointed by the regulating act, came into operation during his administration. This council arrogated to itself authority exceedingly embarrassing to the governor-general, to whom it was very hostile. Hastings used very unscrupulous, and at times very unjustifiable means to replenish the East India company's exchequer, but, by his energy and talent, he averted dangers that threatened to annihilate the British supremacy in India. The powerful Mussulman sovereigns, Hyder Ali and the nizam of the Deccan, assisted by French officers, combined with the Mahrattas against the English; sir Eyre Coote broke up the confederacy, and defeated Hyder Ali in 1781. In 1782 the supreme court of judicature was deprived of its independent powers, and the policy of Hastings was successful both in the council and in the field. In 1784 Mr. Pitt instituted the board of control.

Marquis Cornwallis (1786–93).—Lord Cornwallis, who succeeded Warren Hastings, was both governor-general and commander-in-chief. His administrative measures were important, and consisted most notably in fixing the land-rent throughout Bengal on that

system of land tenure known as Zemindari, and reforming the judicial system. In 1790 lord Cornwallis, with the nizam, the Mahrattas, and the rajah of Coorg for allies, made war on Tippoo, sultan of Mysore, who had invaded Travancore, then under British protection. Terms were dictated to Tippoo at his capital, Seringapatam, and he was compelled to cede half his dominions to the company.—The marquis Cornwallis was succeeded by sir John Shore (1793–98), whose rule was in no respect memorable.

Marquis Wellesley (1798–1805).—The British empire in the east, like that of Napoleon I. in Europe, could only be maintained by constant fighting; it was the price paid for empire, and to stand still was to retrograde. Tippoo Sahib broke his faith by intriguing against the English both with the French and with native princes: his bad faith cost him his crown and his life. In May, 1799, Seringapatam was captured, and Tippoo slain. The Hindu dynasty, displaced by Hyder Ali, was restored, and the administration carried on most successfully for the youthful rajah by col. Wellesley (afterwards duke of Wellington). In the famous battle of Assaye, in 1803, he defeated the Mahrattas under Scindia; and the victories of lord Lake in northern India extended very considerably the dominions of the company. The policy of the marquis Wellesley was, however, too aggressive to suit the views of the East India company, and he was superseded by lord Cornwallis, who only returned to India to die. Lord Minto succeeded from 1806 to 1813.

Nothing of much importance occurred until the marquis of Hastings became governor-general (1813–23). He waged war against the Pindaris, who were entirely suppressed. He had previously defeated the Gurkhas; and before the close of his brilliant administration, he made the British power supreme in India. The civil administration of the marquis of Hastings was directed to the amelioration of the moral condition of the people of India.

The next administrations were those of earl Amherst and lord William Bentinck. The first was signalized by the Burmese war, the second by the suppression of sutti and the thugs.

Earl of Auckland (1835–42).—This governor-general is known chiefly by his unjustifiable and disastrous Afghan policy, ending in the horrible massacre of British troops in the Khyber pass. See AFGHANISTAN.

Earl of Ellenborough (1842–44).—The "army of retribution" proceeded to Cabul soon after lord Ellenborough took the reins of government. Cabul was sacked, several public buildings razed to the ground, after which the country was evacuated. The conquest of Sinde by sir Charles Napier, followed by its annexation, also belongs to this administration.

Sir Henry Hardinge (1844–48).—Lord Ellenborough having been recalled by the East India directors, from alarm at his martial tendencies, sir Henry Hardinge was sent to take his place. The attention of the new governor-general was, however, soon diverted from works of peace, to do battle with the bravest people of India. Ever since the death of our ally, Runjeet Singh, in 1839, the Punjab had been in a state of disorganization. The Sikhs, uneasy at our conquests in Sinde and Gwalior, and remembering our discomfiture at Cabul and the Khyber, resolved to anticipate the attack they considered imminent. The first Sikh war commenced on the part of the Punjabees by the passage of the Sutlej, and was followed by the terrible battles of Moodkee, Ferozeshah, Aliwal, and Sobraon, in which, after very hard fighting, the Sikhs were defeated with great slaughter. The war resulted in a British resident and British troops being stationed at Lahore, although the boy-prince, Dhuleep Singh, was acknowledged as maharajah. The Cis-Sutlej states, the Jullundur Doab, and the alpine region between the Beas and the Sutlej, were annexed.

Marquis of Dalhousie (1848–55).—The administration of the marquis of Dalhousie is memorable for the commencement of superb public works, cheap uniform postage, railways, telegraphs, improvements in government, and social progress generally; a second Sikh war (ending in the crowning victory of Gujerat, Feb. 21, 1849), a second Burman war (finished in 1852); and the annexation of four kingdoms, the Punjab, Pegu, Nagpûr, and Oude.

Viscount Canning (1856–62).—When lord Canning took the reins of government, everything promised a reign of peace and prosperity. With the early days of 1857 came the first mutterings of the storm that was to sweep over so large a portion of British India. At the commencement of the year, chupattees (cakes of flour and water) were circulated mysteriously through the North-west Provinces; treasonable placards appeared at Delhi, and other suspicious occurrences gave warning of Mohammedan disaffection or conspiracy. The Enfield rifle and its greased cartridge was at this time put into the hands of the sepoys without explanation or precaution; and gen. Anson, the commander-in-chief, snubbed caste, and was against all concession to the "beastly prejudices" of the natives. The mutiny broke out at Meerut (32 m. from Delhi), where there were stationed European troops amounting to about 1800 men, besides sappers and miners, and about 2,900 native soldiers. On April 23 the skirmishers of the 3d native cavalry, on parade, refused to touch the new cartridges, although permission was given to break off the end with the fingers. The 85 mutineers were tried, and sentenced to imprisonment. On the evening of the next day, the native troops rose, liberated

their comrades and the felons of the jail, shot down their officers, and the doomed station was given up to conflagration and massacre. The next day, May 11, the Meerut mutineers reached Delhi. There were no European troops to oppose them, and the city fell into their hands, but was retaken by gen. Archdale Wilson the following Sept. Nana Sahib of Bithoor, whose claims as the adopted son of the pishwah had not been recognized by the British government, fanned the insurrection. At the end of June gen. Wheeler was forced to surrender to him at Cawnpore, and, in spite of the promise of safe-conduct to Allahabad, all the men were immediately massacred. The women were butchered on July 15, by order of the nana, when he heard of Havelock's march from Allahabad, which began on the 7th of the same month. The Europeans in the residency at Lucknow were besieged on June 30th. Five days afterwards, the commandant, sir Henry Lawrence, died of his wounds, and his place was taken by brig. Inglis, who bravely held out till he was relieved on Sept. 25 by the heroic Havelock. The final relief was achieved by sir Colin Campbell; and on the 17th the city was again in complete possession of the British. By June, 1858, no city or fortress of any importance remained in the hands of the mutineers. Oude was entirely reduced by the beginning of the year 1859. The able rebel leader, Tantia Topee, a Mahratta Brahman, was taken, tried by court-martial, and hanged. During the mutiny valuable assistance and protection were received from many native chiefs. Honors were, in consequence, bestowed upon Scindia, the maharajah of Gwalior; Holkar, maharajah of Indore; the nizam, and others. The trial of the king of Delhi resulted in his conviction as "a false traitor to the British government, and an accessory to the massacre in the palace." It was the fate of the last representative of the East India company to sentence the last Great Mogul and heir of the house of Timûr "to be transported across the seas as a felon." He was transported accordingly, accompanied by his queen and son, to Tongu, in Pegu, where he died in 1862.

The transfer of the government of India to the British crown, and the new constitution already referred to, were the immediate consequences of the mutiny.

The Earl of Elgin (1862–63).—No event of importance occurred during the brief administration of governor-general lord Elgin, who died in Nov., 1863.

Sir John Lawrence (1863–65).—Towards the close of lord Elgin's administration, a Mohammedan rising was apprehended in n.w. India, and it was considered most desirable that the new viceroy should have practical experience of Indian affairs. Sir John, afterwards lord Lawrence, was accordingly appointed viceroy. He conducted the government with prudence and zeal; but unfortunate events occurred during his term of office. A war with Bhotan terminated rather unsatisfactorily for England in 1865; and a dreadful famine occurred in Orissa, caused by a drought and failure of the crops, by which 1,500,000 people perished.

Earl Mayo (1869–72).—The administration of lord Mayo was inaugurated by a great demonstration at Umballa on March 27, 1869, when the ameer of Afghanistan was received in state, and received a supply of arms and the first installment of a money subsidy of £120,000 a year. In returning from Rangoon to Calcutta, lord Mayo visited a convict establishment in the Andaman islands, and was assassinated there by one of the prisoners in Feb., 1872. The act had no political significance.

Baron Northbrook (1872).—Lord Northbrook entered on office in May, 1872. The chief events of his administration were "the Bengal famine," which, however, was anticipated in good time; and the visit of the prince of Wales to India (1875).

Baron Lytton (1876).—The most important events in the tenure of office of lord Lytton have been the proclamation of the queen as empress of India (1877), the relief of another famine, and the Afghan war (1878–79).

Garcin de Tassy (Paris, 1874).

INDIA, THE NATIVE STATES OF, are divided into those which are entirely independent and those which are more or less under the control of the Indian government. To the former class belong Nepaul (q.v.) and Bhotan (q.v.) To the latter class belong a large number of states, an estimate of the area and population of which is given in the following table:

Native States under the	Area in Sq. Miles.	Population.
Governor-general of India	304,448	26,758,178
Lieutenant-governor of Bengal	38,936	2,271,943
" " N.W. Provinces	6,311	1,091,810
" " Punjab	115,287	5,567,478
Chief Commissioner of Central Provinces	28,834	1,049,710
Governor of Madras	23,200	4,756,235
" Bombay	72,209	8,840,163
Total	589,315	50,325,457

The native princes who profess the Hindu religion are called rajahs and maharajahs; those who are Mohammedan are called nawabs, khans, etc. The following are a few of the most important more or less dependent native states: In the n.w. is Cashmere (with Ladakh), under a native rajah (pop. 3,000,000), a mountainous region of the western Himalaya; the hill states, under a large number of native chiefs (pop. 750,000); Gurhwal, under a rajah (pop. 200,000); Bawalpûr, under a khan, s. of Multan (pop. 1,000,000). The Sikh states, the largest of which is Puttiala (pop. 1,250,000), lie between the Jumna and the Sutlej. The Rajpoot states (pop. 8,500,000) number 18, each under a rajah. The states of Malwa are 21 in number: among the most important are Bhopal (pop. 815,000) and the Bundelcund states (pop. 1,142,000). Gwalior, or Scindia's dominions, includes a number of scattered districts (pop. 3,250,000), situated in the valleys of the Tapti, Nerbudda, and Chumbul. The present maharajah attained his majority in 1853, and was then intrusted with the administration. He has governed the country well, and, as stated above, in 1857 remained faithful to England. Indore, or the Holkar's dominions, lies between the Vindhya and Satpura mountains (pop. 815,000). Gugerat has a pop. of 4,250,000, and Cutch, 500,000; both countries are split up into a number of states. In the Deccan, Hyderabad has an area of 80,000 sq.m; the pop. is about 11,000,000. The country is ruled by the nizam or "regulator;" but sir Salar Jung, many years minister of the late nizam, has, during the minority of the present prince, acted as regent, and discharged the difficult duties intrusted to him with very great ability. Cochin has a population of 500,000, and Travancore of 1,000,000 Mysore (pop. 5,055,412) is a native state, but has long enjoyed the advantages of British rule: it is to be restored to native administration on the maharajah, who in 1874 was 11 years of age, reaching majority. He is under the care of an English tutor, the country being administered by an English commissioner. To these states are to be added those situated in the north-eastern provinces—viz., Sikkim, on the slope of the Himalayas, between Nepaul and Bhotan (pop. 62,000), governed by a rajah; Munipûr, between Assam and Burmah (pop. 75,000), under a rajah; and Independent or Hill Zipperah, a country covered with dense jungles, and inhabited by the Kookies, a savage race, whose chiefs pay tribute to a maharajah. No census of the native states having been taken, the estimates of population must be considered as mere approximations to the truth, on which no great reliance is to be placed.

Further information respecting many of the native states of India will be found under their respective names.

INDIA, FRENCH, comprises, at the present time, the following settlements:

Name.	Locality.	Area in Sq. Miles.	Population, in 1876.
Chandernagore	On the Hoogly river	200	270,500
Karikal	Coromandel coast		
Pondicherry	Coromandel coast		
Yanon	Orissa coast		
Mahé	Malabar coast		

INDIA, PORTUGUESE, is now confined to the territories indicated in the annexed table:

Name.	Locality.	Area in Sq. Miles.	Population.
Goa, etc	Western coast	1400	392,234
Damaun	Concan coast	42	53,283
Diu	South coast of Kattywar		

INDIANA, one of the United States of America, organized in 1816, with a governor and legislature, extends from 37° 47′ to 41° 46′ n. lat., and from 84° 49′ to 88° 2′ w. long., having a length of 275 m., a breadth of 135 m., and an area of 33,809 sq.m., or 21,637,760 acres. It is bounded on the n. by Michigan state and lake, e. by Ohio, s. by Kentucky, from which it is separated by the Ohio river, and w. by Illinois. The state is

divided into 92 counties. The capital is Indianapolis, near the center, and its chief towns are Evansville, New Albany, Madison, Richmond, Terre Haute, Lafayette, Fort Wayne, and its only lake port, Michigan City. The population in 1800 was 4,875; in 1810, 24,520; in 1820, 147,178; in 1830, 343,031; in 1840, 685,866; in 1850, 988,416; in 1860, 1,350,941 (of which nearly half were immigrants from other states, and from Germany and Ireland); and in 1870, 1,680,637. The state is level, with sluggish streams and great prairies. It is chiefly drained by the Wabash river and its branches. There are 7,700 sq.m. of coal, portions of which, on the Ohio, are cannel coal of excellent quality. The soil is of wonderful fertility, and the climate is like that of the s. of France, with colder winters, and the hills on the Ohio are covered with fine vineyards. The staple productions are wheat, maize, cattle, swine, tobacco, fruits, wine, etc. In 1869 mines of coal and iron were found, and also quarries of building-stone. There are over 4,000 m. of railway, and 374 m. of a canal uniting the Ohio river with lake Erie. There is a state university, a normal school, numerous common schools and churches, and about 300 periodicals. Vincennes, on the Wabash, was settled by the French in 1702. Early in this century the settlements were disturbed by Indian hostilities; the Indians were defeated in 1811 by gen. Harrison, and the territory was rapidly peopled.

INDIANA (*ante*), was a part of the territory claimed by the French previous to the cession of Canada to England in 1763. As early as 1702 emigrants from Canada made settlements at Vincennes, Corydon, and other places. They amalgamated with the Indians so far at least as to adopt many of their customs and habits. Soon after the country was transferred to the United States there were troubles with the Indian tribes, which caused great distress among the settlers at Vincennes. These troubles continued for several years, but a temporary peace was conquered by gen. Wayne. In May, 1800, Ohio was erected into a separate territory, while all the region w. and n. was included in the territory of Indiana, organized two months later, with William Henry Harrison as governor. Michigan and Illinois were subsequently organized, reducing Indiana to its present limits. After this the Indians again became troublesome, and the growth of the white settlements was impeded. The census of 1810, however, showed a population of 24,520. The national government, in 1811, determined to subdue the savages, and gov. Harrison was placed in command of a force of regulars and militia for that purpose. Tecumseh, a chief of the Shawnees, was the Indian leader—a man of unbounded influence with his people. Gen. Harrison marched to Tippecanoe on the Wabash, Nov. 16, 1811, and on the following day there was a desperate battle, in which the Indians were defeated, and not long afterwards they sued for peace. When the war with England broke out they rallied again, but were speedily conquered and nevermore troubled the settlers. Dec. 11, 1816, Indiana was admitted to the union, after which the growth of the state in population and wealth was very rapid. Its growth was still further accelerated a few years later by the construction of the national road and the Erie canal, which furnished new outlets for the produce of the west, and greatly diminished the terrors of the journey thither for emigrants from the east. In the ten years ending in 1830, 3,558,221 acres of the public lands were sold in Indiana, mostly to actual settlers. The population in the same time had increased to 343,031. Soon after this the state entered upon several great works of public improvement, by which it incurred a debt of more than $14,000,000, under which it sank into temporary bankruptcy in the financial revulsion of 1837. Notwithstanding this the population of the state doubled in the decade 1830–40 and 9,122,688 acres of public land were sold. It was not until 1846 that the state succeeded in making provision to meet the annual interest upon its debt. This brought prosperity; and since then its growth has been very rapid.

Indiana has no mountains, and fully two-thirds of its surface is level or undulating. The highest elevation is 540 ft. above the level of the Ohio at the mouth of the Wabash. The hills bordering the rivers inclose wooded bottom lands of the richest quality. Many of the hills on the Ohio are as high as the highest interior elevations. At the points where they are broken by tributary streams the scenery is quite picturesque. The table-lands of the interior are either vast level prairies, interspersed with groves of oak, ash, and other trees; or undulatory, with occasional hills rising from 100 ft. to 300 feet. Near the Ohio river some of the land is hilly or sterile, but mostly it is very productive. The principal river valleys are exceedingly fertile. The largest of these n. of the Ohio is that of the Wabash, containing 12,000 sq. miles. The next in size is that of White river, containing 9,000 sq. miles. The valley of the Maumee, in the n.e. part of the state, embraces an area of 2,000 sq. miles. Near lake Michigan on the n. the surface is broken into sand-hills, covered with stunted oaks and pines, but the land a few miles back from the shore is of a very fine quality. The principal streams which flow into the Ohio from Indiana are the Laughery, Indian, Kentucky, Silver, Indian Blue, Big Pigeon, and Little Pigeon, none of which are navigable. The Whitewater, in the e. part of the state, joins the Miami 6 m. above the point where the latter flows into the Ohio. The Wabash rises in Ohio, flows though the state for a distance of more than 500 m., and empties into the Ohio. It has been navigated about 300 m. from its mouth. Tributary to it are Salomonie, Mis-

sissinewa, Wildcat, Sugar or Rock, Raccoon, Patoka, Vermilion, Eel, Little, and White rivers, the latter having its source near the Ohio line. The Maumee is formed in Allen co., in the n.e. section of the state, by the junction of the St. Mary's from the s. and the St. Joseph's from the n., and flows in a n.e. direction through Ohio to lake Erie. The Kankakee, one of the constituents of the Illinois, flows a distance of 100 m. through the n.w. portion of the state. There is also another St. Joseph's in the n.w. part of the state, which rises in Michigan and returns to that state. Lakes and ponds are numerous in the state, most of them n. of the Wabash. Some of them have no outlets; their waters are clear and their shores and bottoms sandy. Beaver lake, near the Illinois line, which once covered an area of 10,000 acres, has mostly been drained off. Bituminous coal of three distinct varieties is found in the state in great abundance. The measures cover an area of nearly 6,500 sq.m. in the s.w. part of the state, extending from Warren co. on the n. to the Ohio river on the s., a distance of 150 miles. The total depth of the measures is from 600 to 800 ft., and they present from 12 to 14 distinct seams, the latter ranging from 1 ft. to 11 ft. in thickness. The celebrated block coal, which is used in its raw state for making pig-iron and is peculiarly suited to metallurgical purposes, is found in the s. zone of the coal measures. It is taken out of the mines in blocks weighing a ton or more. In Daviess co. there is a seam of superior cannel coal. Peat exists also in the n. part of the state; also bog-iron ore, suitable for mixing with the purer ores of Missouri. Quarries of building stone are estimated to cover an area of more than 200 sq. miles. The stone is of great variety in color and grade and of enduring strength. The product of the quarries in 1879 amounted to $500,000. Fire-clays exist also in great abundance. Salt springs are found on the e. border of the coal formation. In Crawford co., in the s. part of the state, is Wyandotte cave, which is only a less interesting phenomenon than the Mammoth cave of Kentucky. The climate of Indiana is marked by extremes and sudden changes. The winds in winter, sweeping over wide spaces without obstruction, are cold and piercing, but they temper the heats of summer. The mean temperature of the year is 52°, of the winter 31°, of spring 51°, of summer 76°, of autumn 55°. Only a small proportion of the land is unavailable for cultivation; one-third of the state is in forest, and one-eighth in prairie. The best lands are the bottoms on the Wabash, White, and Whitewater rivers. Among the forest trees are the oak, beech, sugar-maple, hickory, ash, black walnut, poplar, and sycamore.

As an agricultural state Indiana ranks high. The chief productions are wheat, corn, rye, oats, barley, buckwheat, peas, beans, potatoes, grass, clover-seed, fruit, flax-seed, flax, hemp, hay, tobacco, wool, hops, beef, bacon, pork in bulk, lard, butter, cheese, milk, maple-sugar, maple molasses, sorghum molasses, honey, wax, wine, cider, vinegar, horses, mules, asses, sheep, swine, milch cows, working oxen, and other cattle. Some of the products in 1873 are reported as follows: wheat, 22,149,527 bush.; corn, 81,185,485 bush.; barley, 11,434,628 bush.; fruit, 3,473,161 bush.; tobacco, 12,377,182 lbs.; wool, 2,228,437 lbs.; beef, 3,320,067 lbs.; bacon, 40,716,539 lbs.; pork in bulk, 40,716,539 lbs.; maple-sugar, 302,041 lbs.; wine, 827,480 gall.; cider, 1,097,019 gall.; horses, 514,438; sheep, 1,235,874; swine, 2,999,139; cattle, 1,211,246. The wheat crop of 1879 was estimated at 55,000,000 bushels. The census of 1870 reports the number of farms at 161,289; 55,614 of which contained from 20 to 50 acres each, 52,614 from 50 to 100 acres, 29,433 from 100 to 500 acres, and 1004 from 500 to 1000 acres, while 76 contained upwards of 1000 acres. The cash value of these farms was estimated to be $634,804,189; value of farming implements, $17,676,591; farm wages paid (with board), $9,675,348; total value of all farm productions, $122,914,302; value of orchard products, $2,858,086; home manufactures, $605,639; animals slaughtered and sold for slaughter, $30,246,962; forest products, $2,645,679; live stock, $83,776,762. Coal mined in 1873, 570,382 tons; lime made, 1,167,661 bushels.

Indiana has but one port, Michigan City, on lake Michigan, and no direct foreign commerce: its internal trade by means of its rivers, canals, and railroads, is of vast extent. Evansville, on the Ohio, is a port of delivery of the United States and a place of considerable business. In 1873 there were 3,544 m. of railway track in the state. The most important of the roads are the following: Louisville, New Albany, and Chicago, 288 m.; Ohio and Mississippi, 225; Evansville and Crawfordsville, 109; Fort Wayne, Muncie, and Cincinnati, 108; Indianapolis, Cincinnati, and Lafayette, 158; Indianapolis, Peru, and Chicago, 161; Indianapolis and Vincennes, 116; Jeffersonville, Madison, and Indianapolis, 110; Pittsburg, Fort Wayne, and Chicago, 156; Toledo, Wabash, and Western, 166. The longest canal in the United States is the Wabash and Erie, connecting the Maumee river at Toledo with Evansville on the Ohio. It is 467 m. long, and its course for 374 m. is in Indiana. The Whitewater canal extends from Lawrenceburg on the Ohio to Hagerstown, 75 miles. Neither of these canals is much used. There were in the state, in 1873, 6,943 m. of telegraph, the assessed value of which was $807,874.

The number of national banks in 1873 was 92, with a capital of $17,611,800, and an outstanding circulation of $14,536,015. There were in the state at the same date 125 insurance companies, the gross receipts of which for six months ending July 1, 1873, amounted to $1,169,413. The total valuation of real and personal property in the state in 1873 was $950,467,854. The state debt at the same date was $4,898,657.

The number of manufacturing establishments in 1870 was 11,847, employing 58,852 persons, of whom 54,412 were males above 16 years of age, and 2,272 females above 15; while 2,168, including both sexes, were below 16: capital invested in these establishments,

$52,052,425; wages paid in 1870, $18,366,780; value of products, $108,617,278. The chief branches of manufactures are agricultural implements, boots and shoes, carriages and wagons, railroad cars, clothing, flour, furniture, iron, leather, lumber, liquors, machinery, pork-packing, saddlery, woolen goods, tin, copper, and sheet-iron ware.

The legislature, which meets biennially, is composed of a senate of 50 members, elected for four years, and a house of representatives of 100 members, elected for two years. The governor and lieutenant-governor are elected for four years, the former having a salary of $8,000 a year. Members of the legislature are paid $8 per day during the session. The supreme court consists of five judges, elected by the people for a term of six years, and receiving an annual salary of $4,000 each. The circuit judges, 38 in number, are elected by the people for terms of six years, and receive salaries of $2,500 each. The law provides for a superior court of three judges, elected for a term of four years, in any county containing a city of 40,000 inhabitants. Marion co., containing Indianapolis, the state capital, is the only one to which this provision is applicable. Every male citizen of the age of 21 years, who has resided in the state six months, has the right to vote. Women are eligible to any office in the gift of the governor or the legislature. The divorce laws, which were formerly very elastic, are now more strict. Divorce is allowed for seven different causes, including cruel and inhuman treatment, habitual drunkenness, and failure of the husband for two years to make provision for the support of his family.

The principal public institutions supported wholly or partly by the state are the hospital for the insane, and the institutions for the deaf and dumb and the blind at Indianapolis; the house of refuge at Plainfield; the soldiers' home at Knightstown; the northern state-prison at Michigan City, and the southern state-prison at Jeffersonville; the reformatory institution for women and girls in Indianapolis; the normal school in Terre Haute; the state university at Bloomington; and the agricultural college at Lafayette. An act was passed in 1879 to provide for the organization and support of the feeble-minded.

The state board of education is composed of the governor, the superintendent of public instruction, the presidents of the state university and the normal school, and the school superintendents of the three largest cities in the state. The common schools are under the immediate supervision of the state and county superintendents, and the trustees of educational affairs in cities and towns. Instruction is afforded without charge for tuition to all persons between 6 and 21 years of age; separate schools being provided for negroes. The permanent common school fund of the state amounted in 1874 to $8,616,931, yielding an annual income of $189,455. Besides this there is an annual poll-tax and a property tax of 16 cents on the $100 for school purposes. The income from these sources, added to the interest on the permanent fund, swelled the amount of school revenues in 1873 to $2,276,569. The whole school population of the state in 1872 was estimated at 640,332; the number of pupils enrolled was 465,154, of whom 13,895 were in high schools; average attendance, 298,851; number of teachers employed, of whom a majority were males, 12,056; total valuation of school property in 1872, $9,199,480. In 1879 the school population of the state was 707,845; average daily attendance, 312,143; number of teachers, 13,490; total school revenue, $4,902,163; value of permanent school property, $12,000,000. Besides the state university and the agricultural college, there are 16 institutions of learning that have no connection with the state. The most important of these are the university of Notre Dame (Roman Catholic), the North-western Christian university (Disciples), Asbury university (Methodist), Earlham college (Friends), Wabash college (Presbyterian). St. Mary's academy at Notre Dame, Logansport female college, De Pauw college at New Albany, and the Indianapolis institute afford superior instruction for girls. The total number of educational institutions in the state in 1870 was 9,073, with 11,652 teachers, of whom 4,974 were females; and 464,477 pupils. The number of libraries in 1870 was 5,301, containing 1,125,553 volumes. The most important of these are the state library at Indianapolis, and the libraries of Wabash college, Notre Dame university, Hanover college, State university, and the North-western Christian university. According to the census of 1870 there were in the state 293 newspapers and periodicals, with an aggregate circulation of 363,542 copies. Of these publications 20 were daily, 3 tri-weekly, 1 semi-weekly, and 233 weekly, 6 semi-monthly, 2 monthly, and 2 bi-monthly. The religious organizations at the same time numbered 3,698; the church edifices 3,106; value of church property, $11,942,227. The principal religious denominations were the Baptist, Christian, Congregational, Episcopal, Friends, Lutheran, Methodist, Presbyterian, Reformed (Dutch, and German), Roman Catholic, United Brethren in Christ, and Universalist.

The electoral votes of Indiana for president and vice-president have been cast as follows:—1816, 3 for Monroe and Tompkins; 1820, 3 for Monroe and Tompkins; 1824, 5 for Jackson and Calhoun; 1828, 5 for Jackson and Calhoun; 1832, 9 for Jackson and Van Buren; 1836, 9 for Harrison and Granger; 1840, 9 for Harrison and Tyler; 1844, 12 for Polk and Dallas; 1848, 12 for Cass and Butler; 1852, 13 for Pierce and King; 1856, 13 for Buchanan and Breckinridge; 1860, 13 for Lincoln and Hamlin; 1864, 12 for Lincoln and Johnson; 1868, 13 for Grant and Colfax; 1872, 15 for Grant and Wilson; 1876, 15 for Tilden and Hendricks; 1880, 15 for Garfield and Arthur.

INDIANA, a co. of w. central Pennsylvania, 770 sq.m.; pop. '70, 36,138. It is drained by the Mahoning, Black Lick, and Two Lick creeks. The surface is hilly and covered with forests, chiefly white pine. The soil is generally fertile. The staple products are

wheat, oats, buckwheat, maize, hay, and cattle. Mines of bituminous coal and iron ore, and salt-springs, are numerous. There are many manufactories, flour mills, tanneries, saw and planing mills. Cap., Indiana.

INDIANA ASBURY UNIVERSITY, at Greencastle, Putnam co., Ind., a Methodist institution, was organized in 1835. Number of instructors in 1878, 17; of students, 364. President, Alexander Martin, D.D., LL.D.

INDIANA'POLIS, a city and capital of Indiana, United States, is built on the w. fork of White river, near the center of the state, 100 m. n.w. of Cincinnati. It is a regularly built and beautiful city, with a handsome state-house, court-house, jail, and state asylums for the blind, deaf and dumb, and insane. It has a university, 2 female colleges, 64 churches, 8 banks, several printing-offices, hotels, woolen factories, iron-foundries, planing-mills, and flour-mills, with abundant water-power. It is the terminus of ten radiating railways. In 1840 the pop. was 2,692; in 1870, 48,244.

INDIANAPOLIS (*ante*), was selected in 1820 as the seat of government, and made the capital of the state in 1824. Pop. '80, 76,200. It is situated on a plain on the e. bank of the river. From a small park in the center four broad avenues diverge, intersecting the streets, which are very wide and run at right angles. The streets are generally graveled, but many are paved with stone or wood, and all lighted with gas. Nine bridges, all but one of iron, three of which are for railroad trains, cross the river here. The street railroads have 50 cars. There are 7 parks; that in the n. part of the city containing 100 acres. Thirteen railroads center here which, with their numerous branches, traverse the state, and connect its rich agricultural and mineral districts with the chief cities of the west. A belt-line around the city was commenced in 1875 for the purpose of connecting all the other lines. Eighty-two passenger trains, with over 300 cars, daily leave and enter the union depot, with an average of 10,000 persons, and the number of freight cars entering and leaving in 1874 was above 700,000. There are two large grain elevators, 10 flouring mills, and 8 pork-packing establishments. The manufactures of the city are varied and extensive, having 2 iron rolling mills, 20 foundries and machine-shops, car-works, factories for agricultural implements, sewing-machines, organs, pianos, carriages, household and school furniture, sash, blinds, glass, starch, glue, cotton and woolen goods, wooden ware, etc. The number of incorporated manufacturing institutions is 30, with an invested capital of $15,000,000. There is an efficient fire department, with 7 engines and a complete fire-alarm telegraph. The city is abundantly supplied with water by the Holly system. There are 6 national, several private, and 2 savings banks, many insurance companies, 70 churches, state asylums for the deaf and dumb, blind, and insane, a university, 2 medical colleges, a law school, a Roman Catholic theological seminary, a city hospital, an art school, an academy of music, a state library with 15,000 volumes, and a free city library with 14,500, a splendid court house, an exposition building, a chamber of commerce building, Odd Fellows' and Masonic halls, the union depot, U. S. arsenal, and many other fine massive buildings. A new state house; to cost $4,000,000, has been authorized by the legislature. The city has a well-organized system of public schools, containing over 20,000 pupils, a high school and a normal school. The public schools are supported from the state school fund of $8,000,000, and by state and local taxation.

The sales of real estate in 1873 amounted to $32,579,253. The taxable value of property in '73 was $65,000,000. The city was incorporated in 1836.

INDIAN ARCHIPELAGO. See MALAY ARCHIPELAGO, *ante*.

INDIAN ARCHITECTURE. The styles of art which have existed at different times in India, as in other countries, vary with the religion prevalent at the time. The earliest faith of which we have any architectural monuments is that of Buddhism (q.v.). About 250 B.C. Asoka, a powerful monarch, became a strenuous supporter and propagator of Buddhism, and to his zeal we owe the oldest architectural remains of India. From his time to the present day the sequence is unbroken, and the whole history of Buddhist architecture can be most distinctly traced either in India or in Ceylon, Java, and Thibet. The whole subject is as yet, however, but imperfectly illustrated, the best account of the Indian styles being that contained in Fergusson's *Handbook of Architecture*, and his other works.

The Buddhist remains are of two kinds: 1. Commemorative monuments, called stupas or topes (q.v.); the earliest stupas are single pillars, bearing evident traces of a western origin, and thus affording a clue to the history of Indian art. 2. Temples (chaityas) and monasteries (viharas). Of the chaityas and viharas no built examples remain; they are all excavated out of the solid rock. There are no less than 40 or 50 groups of these monuments, each group comprising from 10 to 100 distinct excavations. A few of these belong to other religions, but the great majority are Buddhist, and nearly the whole are monasteries, not over 20 to 30 being temples. The oldest are at Bahar and Cuttack in Bengal (200 B.C.), but they are few in number, nine-tenths of the caves being in the Bombay presidency. This probably arises from the nature of the material in which they are cut, the eastern caves being in a hard granite, and those of the west being in a very uniform and comparatively soft amygdaloid. The latter date from the beginning to to about the 10th c. of the Christian era. The cave-temple at Karli is one of the largest,

and is of a good style. (See section in art. BUDDHA.) In plan and general arrangements, it strongly, though no doubt accidentally, resembles a Christian basilica, with nave, aisles, and vaulted roof, and an apse with the shrine in the place of the altar. There is also an outer hall or atrium, and a gallery like the rood-loft. On the roof are numerous wooden ribs, attached to the vault; these and other portions indicate that the building from which the cave was copied was wooden, which may account for the absence of earlier built examples. This cave is 126 ft. long, 45 ft. 7 in. wide, and 40 to 45 ft. high.

The vihara or monastery caves are very numerous, as was required by the enormous number of Buddhist priests. The oldest and simplest examples are in Bengal, but the finest are in western India. They consist of a central hall, with cells round three sides, and a verandah on the fourth side, next the open air; opposite the central entrance there is usually a large cell or shrine, containing an image of Buddha. There are fine caves at Ajunta, Baugh, etc., many of them beautifully carved and painted. The pillars are most elaborately ornamented, and have the bracket capitals which distinguish all Indian architecture. From the absence of any built example, there has been great difficulty in forming a correct idea of the exterior of the buildings from which these caves were copied. By following the style into other countries where the religion has prevailed at different times, Mr. Fergusson has been able to trace it up to the present day, and to establish by analogy the probable external appearance of the early Buddhist architecture.

The temple of Brambanam, in Java, seems to show the original form of built cells. They are quite detached, and arranged in a square round a central temple—evidently suggesting the arrangement in the caves at Ajunta. Some rock-cut temples which have an exterior (at Mahavellipore), show the cells attached to the main building. In Burmah, where the monastic system still prevails, the monasteries, which are of wood, are built in stages in a pyramidal form. The temple of Boro Buddor (q.v.), in Java, has a similar arrangement, consisting of a large number of cells or niches in tiers; but in place of being occupied by priests, they are filled with cross-legged Buddhas, a conversion quite common in later Hindu architecture. In many styles of architecture the niches or other subordinate parts are frequently copies on a small scale of the façade of the building itself. Thus, for instance, the windows with pillars and pediments in classic architecture, are a repetition of a temple end. The niches inside the caves, containing statues of Buddhist saints, are in a similar manner imitations of the main façade. In the same way externally the Burmese pagodas and Hindu temples are ornamented all over with models of the buildings themselves.

Mr. Fergusson has thus traced, in fuller detail than our space will allow, the transformations that have taken place in Buddhist architecture, which, whatever its artistic qualities may be, has at least the very interesting feature of being a style which has existed from 200 years before Christ up to the present day.

The other styles of Indian architecture are illustrated by the temples of the Jainas and those of the Hindus. The former seems to have been an imitation of the Buddhist temples without the cells for the priests. Their religious structures consist of a sanctuary surmounted by a spire; in front of this a pillared vestibule, with a dome, and round the whole an arcaded inclosure, with cells all round, containing images. The cells are also surmounted with spires, and the arcades with domes are often repeated to a considerable number within one inclosure. The most striking feature of this style is the dome, which is constructed by horizontal jointing, not with regular arches. The domes, with the pillars, bracket capitals, etc., are all elaborately decorated.

Hindu architecture is divided into two styles—northern and southern. All the finest examples are southern, and are found s. of Madras. The temples consist of the temple or vimana, in front of which is the pillared porch or mantopa, the gate pyramids or gopuras, forming the entrances to the inclosure, and the pillared halls or choultries. In the s. the temple is always pyramidal, and in many stories; in the n. the outline is curved, and in one story. The finest example is the pagoda of Tanjore. It is 82 ft. sq. at base, and 14 stories, or about 200 ft., in height.

The gopuras are similar to the pagodas, but oblong in place of square.

The pillared halls are very wonderful structures, containing sometimes as many as 1000 columns, and as these are all elaborately carved, and all different, the labor of their construction must have been enormous. They are used for many purposes connected with Hinduism, their most important use being as nuptial halls, in which the mystic union of the divinities is celebrated. The general arrangement of these halls sometimes produces a good effect; but from their flat roofs they cannot equal the beauty of the domed arcades of the Jains. These buildings are of various dates, from the commencement of the Christian era to the last century, and it is remarkable that the oldest examples are the finest—the style growing gradually more and more debased, till, at the present day, it has become, like the religion, a mass of absurdity and obscenity. The celebrated rock-cut temple, called the Kylas, at Ellora (q.v.), belongs to this style.

When the Mohammedans conquered India they imitated the style of the country in their mosques, and afterwards the Hindus borrowed from them, and thus a mixed style was created, which, in the palaces, tombs, etc., of the native princes, produces picturesque effects. The Mohammedans also covered the country with specimens of their Moorish style, which will be treated under SARACENIC ARCHITECTURE.

Some of the finest buildings of India are the ghauts or landing-places, with their broad flights of steps; the reservoirs or bowlees, and dams, all ornamented with temples, kiosks, stairs, etc.; but our space will not permit us further to describe them. There is one very remarkable fact connected with Indian architecture, viz., that although the form of the arch is constantly used—in domes, arcades, etc., especially in the style borrowed from the Moslems—yet the radiating arch construction is never adopted. The architraves are supported on bracketed capitals, which project, bracket over bracket, till the space is spanned by one lintel. This leads to many beautiful results in the early styles, and in the later mixed style, the bracketed cornices are amongst it finest features.

INDIAN ARMY. See EAST INDIA ARMY.

INDIANA UNIVERSITY, at Bloomington, Monroe co., Ind.; unsectarian; founded in 1828. Professors in 1878, 16; students, 141. Lemuel Moss, D.D., president.

INDIAN CORN. See MAIZE.

INDIAN CRESS. See TROPÆOLUM, *ante*.

INDIAN CUCUMBER, *Medeola Virginica*, a member of the lily family growing in rich damp woods, from Canada to Florida. It is a perennial herb with a simple slender stem from 1 to 3 ft. high, covered with a flocculent, deciduous wool, and rising from a horizontal white root-stock resembling a cucumber in form, and having a similar taste. The stem bears near its middle a whorl of from 5 to 9 obovate-lanceolate, parallel-ribbed thin leaves, and another whorl of 3 (sometimes 4 or 5) leaves at the top, within which there is a sessile umbel of small, recurved flowers having 3 sepals and 3 petals, 6 stamens. Berry globose and of a dark purple, 3-celled, few-seeded. The botanical name is from Medea, the sorceress, because of supposed medicinal virtues.

INDIAN DYE. See PUCCOON.

INDIAN FIG. See PRICKLY PEAR.

INDIAN FIRE, a bright white signal-light, produced by burning a mixture of 7 parts of sulphur, 2 of realgar (q.v.), and 24 of niter.

INDIAN GRASS MATTING, or INDIAN MATTING, a kind of matting imported in large quantities from Calcutta, is made from a species of papyrus (q.v.), *P. Pangorei*, called *Madoorkati* in Bengal, and there very abundant. The stalks of the plant, when green, are split into three or four pieces, which, in drying, contract, so that the edges come almost into contact; and when woven into matting they show nearly the same beautiful shining surface on both sides.

INDIAN HEMP. See HASHISH, HEMP, INDIAN, *ante*.

INDIAN INK. The cakes of this substance, which is a mechanical mixture, and not, like the true inks, a chemical compound, are composed of lampblack and size or animal glue, with a little perfume. The lampblack must be remarkably fine, and is said to be made in China by collecting the smoke of the oil of sesame. A little camphor (about 2 per cent) is also found in the ink made in China, and is thought to improve it. This substance is used in that country with a brush both for writing and for painting upon paper of native manufacture, while, in this country, it is extensively employed for designs in black and white, and all intermediate shades of color. Much curious information on this pigment may be found in Merimée's treatise, *De la Peinture à l'Huile*.

INDIAN OCEAN, one of the five grand divisions of the universal ocean, is bounded on the s. by a line drawn from the cape of Good Hope to the most southerly extremity of Tasmania or Van Diemen's Land. Its other limits, reckoning from the last-mentioned point, are Van Diemen's Land, Australia, the Indian archipelago, Farther India, Hindustan, Persia, Arabia, and Africa. Gradually narrowing from s. to n., the Indian ocean forks at cape Comorin into the bay of Bengal on the e., and the Arabian sea on the w., the latter again branching off into two arms, the Persian gulf and the Red sea, which reach respectively the mouth of the Euphrates and the neighborhood of the Mediterranean. These details exclude the waters of the Indian archipelago, as belonging rather to the Pacific ocean. As above defined the Indian ocean stretches in lat. from 43° 35′ s. to 30° n., and in e. long. from 18° 29′ to 146° 12′. It contains thousands of islands, or rather tens of thousands. Of these Madagascar is the largest, and at about the same distance from it to the e. as the continent of Africa is to the w., lie Bourbon or Reunion towards the s., and Mauritius towards the north. Next in size to Madagascar, and, in fact, the only other island of any considerable magnitude, is Ceylon. As a channel of commerce this ocean would appear to have been the first to find a place in history, inasmuch as the earliest voyage on record beyond the land-locked Mediterranean—that of Solomon's navy—did certainly extend further than the straits of Bab-el-Mandeb. In this respect it virtually maintained its superiority during fully 2,000 years, being habitually traversed, in the line of the crow's flight, between Arabia and Hindustan, while coasting voyages alone were known in the Atlantic. This comparatively bold navigation was suggested and facilitated by the periodical monsoons of the northern part of the Indian ocean, blowing, as they do, alternately from the s.w. and the n.e.

INDIANOLA, capital of Calhoun co., Texas, a port of entry on the w. shore of Matagorda bay, 14 m. from the gulf of Mexico, and 120 m. s.w. of Galveston; pop. '70, 1900. It is the terminus of the Gulf, Western Texas, and Pacific railroad. It has a large and commodious harbor. Steamers sail regularly to Galveston, Corpus Christi, New Orleans, and New York, and the commerce is important. Cattle are the chief article of export. The town has a weekly newspaper and 2 banks. Sept. 15, 1875, the coast was visited by a severe storm of five days, when Indianola was submerged and nearly destroyed.

INDIAN POKE. See HELLEBORE, *ante*.

INDIAN RIVER, a tidal inlet of Florida, in Brevard and Volusia counties, running nearly parallel with and near the coast. Its length is 100 miles. Its width varies, the inlet in some parts expanding into large lakes or lagoons, and its depth admitting vessels drawing 5 feet. It communicates by canal with Halifax river, and continues southward to St. Lucie sound. The climate being healthful and the scenery beautiful, it is a resort for invalids.

INDIANS, AMERICAN, the collective name now generally given to the various nations and tribes inhabiting North and South America, at the time of their discovery by the Spaniards, and to such of their descendants as survive at the present day. The name of Indians was first given to the natives of America from the mistaken notion of the early voyagers, Columbus himself included, that the newly found continent was in reality a part of India. This was soon shown to be an error; but the name of Indians, thus wrongly applied to the inhabitants, continued to be used in every narrative of voyage and discovery, and has descended even to our own times, only that we now qualify it in some measure by speaking of them as *American Indians*.

In the classification of Blumenbach the American Indians are treated as a distinct variety of the human race; but in the threefold division of mankind laid down by Dr. Latham, they are ranked among the Mongolidæ. Other ethnologists also regard them as a branch of the great Mongolian family, which, at a remote period of the world's history, found its way from Asia to the American continent, and there remained for thousands of years separate from the rest of mankind, passing meanwhile through various alternations of barbarism and civilization. Morton, however, the distinguished American ethnologist, and his disciples Nott and Gliddon, claim for them a distinct origin, one as indigenous to the continent itself as its fauna and flora. Prichard, whose views generally differ from those of Morton, acknowledges that "on comparing the American tribes together, we find reasons to believe that they must have subsisted as a separate department of nations from the earliest ages of the world. Hence, in attempting to trace relations between them and the rest of mankind, we cannot expect to discover proofs of their derivation from any particular tribe or nation in the old continent. The era of their existence as a distinct and insulated race must probably be dated as far back as that time which separated into nations the inhabitants of the old world, and gave to each branch of the human family its primitive language and individuality." Dr. Robert Brown, in his *Races of Mankind*, the latest authority on the subject, attributes to the American race an Asiatic origin. He says: "Not only are the western Indians in appearance very like their nearest neighbors, the north-eastern Asiatics, but in language and tradition, it is confidently affirmed, there is a blending of the people. The Eskimo, on the American, and the Tchuktchis, on the Asiatic side, understand each other perfectly." In fact, modern anthropologists incline to think that Japan, the Kuriles, and the neighboring regions may be regarded as the original home of the greater part of the American race. It is also admitted by anthropologists that between these various tribes, from the Arctic sea to cape Horn, there is greater uniformity of physical structure and personal characteristics than is seen in any other quarter of the globe. The "red men," as they are called, of the United States and Canada, differ in many respects from the Guranis of Paraguay, and both from the wild tribes of California, but all exhibit the clearest evidence of belonging to the same great branch of the human family. Upon this point the testimony of a writer like Humboldt is very important. "The Indians of New Spain," says Humboldt, "bear a general resemblance to those who inhabit Canada, Florida, Peru, and Brazil . . . . We think we perceive them all to be descended from the same stock, notwithstanding the prodigious diversity of their languages. In the portrait drawn by Volney of the Canadian Indians, we recognize the tribe scattered over the savannahs of the Apure and the Carony. The same style of features exists in both Americas." The Mongolian cast of features is most marked in the tribes nearest the Mongol coast, i e., on the shores of the Pacific, and gets less noticeable as we go eastward. Their traditions, too, indicate that the tribes on the eastern seaboard came from the w., and the western tribes even came from regions still further west.

Generally the physical characteristics of the American Indians are as follows: a square head, with a low but broad forhead, the back of the head flattened, full face, and powerful jaws; cheek-bones prominent; lips full; eyes dark, and deeply set; the hair long, not absolutely straight, but wavy, something like a horse's mane, and like that, of a glossy hue; little or no beard—where it does appear, carefully eradicated with tweezers; color of the skin reddish or copper; height of the men about the average, but looking taller from their erect posture and slender figure; the women rather shorter, and more inclined

to obesity, but many of them with symmetrical figure and pleasing countenance; hands and feet of both men and women small.

As before said, however, there being some hundreds of tribes among the American Indians, there are many departures from these general characteristics, not only in individuals, but entire septs. "The Americans," says Prichard, "are not all of the hue denominated *red*, that is, of a copper color; some tribes are as white as many European nations; others brown or yellow; others are black, or, at least, they are described by travelers as very much resembling in color the negroes of Africa. Anatomists have distinguished what they have termed the American form of the human skull: they were led into this mistake by regarding the strongly marked characteristics of some particular tribes as univeral. The American nations are spread over a vast space, and live in different climates, and the shape of their heads is different in different parts. Nor will any epithet derived from their habits of life apply to all the tribes of this department. The native Americans are not all hunters: there are many fishing tribes among them; some are nomadic; others cultivate the earth, and live in settled habitations; and of these a part were agriculturists before the arrival of the Europeans; others have learned of their conquerors to till the soil, and have changed the ancient habits of their race, which, as we may hence infer, were not the necessary result of organization or congenital and instinctive propensity." Dr. Morton's views on this subject substantially agree with those of Prichard; and both concur in adopting the test of language as a proof of one common origin for the various native tribes of both North and South America. The linguistic conclusion, now generally acquiesced in, is thus briefly stated by Mr. Albert Gallatin: "Amidst that great diversity of American languages, considered only in reference to their vocabularies, the similarity of their structure and grammatical forms has been observed and pointed out by the American philologists. The result appears to confirm the opinions already entertained on that subject by Mr. Du Ponceau, Mr. Pickering, and others; and to prove that all the languages, not only of our own Indians, but of the native inhabitants of America, from the Arctic ocean to cape Horn, have, as far as they have been investigated, a distinct character common to all, and apparently differing from any of those of the other continents with which we are most familiar."

The next question that comes under consideration is: Whence does it arise that, with all this similarity of physical conformation and language, there should have been only two nations among so many millions—namely, the Mexicans and Peruvians—who attained to any high degree of civilization? When the Spaniards entered Mexico they found in it a rich, powerful, and warlike nation, living in walled cities, in which were palaces and other sumptuous residences. They were ruled over by an emperor or king, whose sway extended over many other nations besides his own. They worshiped the sun, and had an organized hierarchy; they had also fixed laws, were acquainted with many of the arts and sciences, especially astronomy; they practiced agriculture, worked mines, and displayed considerable skill in manufactures, both industrial and ornamental. The nation thus discovered was that of the Aztecs, who professed to have among them evidences of antiquity dating as far back as the year 554 of our era. A few years later, in Peru, the Spaniards found another nation, also exceedingly rich, numerous, and powerful, with a civilization fully as much extended as that of the Aztecs, yet differing from that in many essential particulars. This was the nation of the Quichuas, frequently termed Incas (more correctly *Yncas*), associated with whom were the Aymaras, whose country had been subjugated by the Incas two or three centuries before the arrival of Pizarro in Peru. Each of these nations—the Mexicans and Peruvians—is supposed to have slowly developed its own civilization during a long process of ages. In every other part of America European settlers and explorers have found only complete or semi-barbarism. Such was the case in Virginia; such in New England, Canada, the Hudson's bay territory, California, and Patagonia. In Central America, however, there have been found extensive remains of architecture and other traces of civilization, which would seem to date back to even a more remote period than that of the Mexican or Peruvian empires. Immense artificial mounds also exist in the valley of the Mississippi and elsewhere throughout America, supposed to be the work of the ancestors of the present wandering tribes. If so, there may be some truth in the theory of Dr. Martius, a distinguished German ethnologist, "that the nations of the new world are not in a state of primitive barbarism or living in the original simplicity of uncultivated nature, but that they are, on the contrary, the last remains of a people once high in the scale of civilization and mental improvement, now almost worn out and perishing, and sunk into the lowest stage of decline and degradation." Dr. Prichard appears inclined to the same view, adding: "Attentive observers have been struck with manifestations of greater energy and mental vigor, of more intense and deeper feeling, of a more reflective mind, of greater fortitude, and more consistent perseverance in enterprises and all pursuits, when they have compared the natives of the new world with the sensual and volatile, and almost animalized savages who are still to be found in some quarters of the old continent. They have been equally impressed by the sullen and unsocial character, by the proud apathetic endurance, by the feeble influence of social affections, by the intensity of hatred and revenge, and the deep malice-concealing dissimulation so remarkable amid the dark solitudes of the American forests."

Dr. Robert Brown adopts a geographical classification of the American tribes, which

is, on the whole, the least unsatisfactory. There are Arctic tribes; north-western tribes inhabiting the region w. of the Rocky mountains between California and Alaska; Californian tribes; Indians of the central plains; prairie tribes; north-eastern Indians; Canadian Indians; and Central American Indians. The chief existing tribes are: Eskimo, Cowichans, Tsongeisths, Nanaimos, Quakwolths, Nuchultaws, Koskeemos, Seshahts, Nittinahts in Vancouver island; Hydahs (Queen Charlotte islanders); Tsimpsheans, Bellacoolas, Chilcoatins, Shuswaps in British Columbia; Cyuse, Snakes, Klamaths in Oregon; the Digger or Californian Indians, the most degraded of all the tribes; the Comanches, Apaches, Navajos, Hualpais, Yampas in the central plains; the Moqui, Pueblos, Pimas, Papagos in New Mexico, Utahs, Pahutas, Pahides, Soshones, Loo-coorekahs, Goships, Cheyennes, Arrapahoes, Kwivas, Arickarees, Poncas, Yanktons, Gros-Ventres, and Sioux or Dakotahs, Assiniboines, Blackfeet, Crows, Omahas, Ottoes, Pawnees, etc., are all prairie tribes; the Delawares, Mo-hee-con-neughs (Mohicans), Oneidas, Tuskaroras, Senecas, Shawnees, Cherokees, Chocktaws, Creeks, Seminoles, Csages, Kaskias, Weeahs, Potowatomies, Quapaws, Peorias, Kanzans, Sauks, Foxes, Puncas, etc., in the north-eastern states; the Crees, Santeux or Ojebways, Chippewayans, the Sacliss or Shewhapmuch in Canada; Tehuantepecs, Mosquitos, Smoos, Twakas, Toonglas, Payas, Ramas, and Cookras in Central America.

The Indians are year by year decreasing in numbers. The government agents' reports are not very reliable, as they tend to over-estimate the Indian population. Dr. Robert Brown, whose classification is given above, gives some carefully prepared approximate statistics in his *Races of Mankind*. He says: "In California and the states n. of it I question if there are now over 10,000 or 12,000 Indians; while in the British possessions the number may be 30,000." A fair estimate would probably give Alaska 20,000; British Columbia, 20,000; Vancouver's island, 9,000; Canada, 5,000; California, Oregon, and states n. of it, 10,000; prairie lands w. of the Rocky mountains, 10,000; other portions of the United States, 2,000; in New Mexico and Central America, 20,000. This would give us a total of about 110,000 for the whole of North America, exclusive of half-breeds, etc. Some twenty tribes have become partially civilized, and live by agriculture, under the protection of the American government, on what are called "Indian reservations." There are in these Indian communities many men and women whom education has developed into most valuable, intelligent, and even polished members of a highly civilized community. Two tribes (Choctaws and Cherokees) have become wholly civilized, and have a settled form of government modeled on that of the United States. The Cherokees stand alone amongst modern nations in having produced a second Cadmus, one Sequoyah, or George Guess, who actually invented an alphabet. It must be stated, however, that fully one-half of these civilized tribes are, like Sequoyah, half-breeds. Even whites marrying Choctaw or Cherokee women are admitted, if they choose, into these tribes.

Again, M. d'Orbigny has classified the Indians of South America under three great groups, viz.: the Andian group, the Mediterranean group, and the Brazilio-Guarani group: and these he subdivides into thirty-nine distinct nations, viz.: "1, Quichua; 2, Aymara; 3, Chango; 4, Atacama; 5, Yuracares; 6, Mocetenes; 7, Tacana; 8, Maropa; 9, Apolista; 10, Araucananian; 11, Fuegian; 12, Patagonian; 13, Puelche; 14, Charrua; 15, Mbocobi; 16, Mataguayo; 17, Abipones; 18, Lengua; 19, Samucu; 20, Chiquito; 21, Saraveca; 22, Otuke; 23, Curuminaca; 24, Covareca; 25, Curaves; 26, Tapiis; 27, Curucaneca; 28, Paiconeca; 29, Corabeca; 30, Moxo; 31, Chapacura; 32, Itonama; 33, Canichana; 34, Movima; 35, Cayuvava; 36, Pacaguara; 37, Itenes; 38, Guarani; 39, Botocudo." Other classifications have been attempted, but all more or less arbitrary. Morton is content with two grand divisions, viz., the "Toltecan nations" and the "barbarous tribes," the former embracing the ancient Mexicans and Peruvians, and the latter all the uncivilized or semi-civilized tribes from the extreme n. to the extreme south. The Toltecans are said to be the builders of the remarkable series of mounds found throughout North America.

On this subject the reader may consult the works of Prichard, Latham, Morton, Humboldt, Du Ponceau, D'Orbigny, Gallatin, Schoolcraft, Catlin, Pickering, Prescott, Stephens, Tschudi, Fremont, and G. M. Sproat, a recent ingenious writer on western tribes. The ablest recent original authority is Dr. Robert Brown's *Races of Mankind* (vol. i.).

INDIANS, AMERICAN (*ante*). The early English and French settlers of North America were often at war with the Indians, either in self-defense or instigated by a desire for their lands. In Virginia the Indians who had combined to exterminate the whites were subdued after a ten years' war. In New England (1637) the colonists of Connecticut and Massachusetts destroyed the warlike Pequods, and in 1643 the Narragansetts. The war of Philip, king of the Wampanoags, ended, 1676, in the almost total destruction of that tribe. The Dutch in New Amsterdam and the English in North and South Carolina suffered greatly from the Indians. In the seven years' war between the English and the French the Indians were used by both sides, and terrible atrocities were committed. In 1763 a number of tribes were united under Pontiac, the chief of the Ottawas, in a general conspiracy to exterminate their conquerors, but were finally subdued. When the American revolution began the Indians, who were allies of the Eng-

lish, ravaged the frontiers. The United States, by the constitution of 1787, claiming sovereignty over the whole territory, made treaties with the Indians for the purpose of obtaining their lands; but in 1790 the Miamis and other tribes conspired and defeated the army under gen. Harmar, and the following year under gen. St. Clair, but were subdued by gen. Wayne. In 1811 they recommenced hostilities under Tecumseh, but were defeated at Tippecanoe by gen. Harrison, who also, in 1812, defeated the combined forces of the English and Indians, and killed Tecumseh. In the s. the Creeks were conquered by Jackson in 1813, and the Seminoles of Florida in 1817. In 1832 the Sacs and Foxes, under their chief Black Hawk, harassed the frontier settlements, and from time to time the Sioux, the Comanches, and Apaches, often joined by other tribes, have given the government great trouble.

In 1838 the Cherokees and Creeks were removed from Georgia to the Indian territory w. of the Mississippi, which the government had established to be the permanent home for all the Indians. The Seminoles of Florida refusing to remove, a bloody war ensued, which lasted seven years and cost $15,000,000. After the removal of the Choctaws, Creeks, and other tribes to the Indian territory, other reservations were formed in several states. In 1871 there were on reservations 237,478, which, added to 60,000 in Alaska, and about 50,000 others not yet placed in reservations, make the total number of Indians in the United States, as estimated by the Indian department, 350,000. The number in the British colonies is estimated at 150,000.

The five civilized tribes of the Indian territory had under cultivation (1879) 237,000 acres, on which they raised over 3,000,000 bush. of cereals, and were engaged largely in the raising of stock. The Indians on other reservations had under cultivation 157,056 acres, and raised over 1,500,000 bush., and all together about 225,000 tons of hay. The Indians are scattered over a large extent of country, and the difficulty of managing them is increased by the attempts of bold and unscrupulous white men to invade their reservations for trade, which often involves fraud, and for the sake of the mineral deposits known to be there. The Utes in Colorado and Apaches in New Mexico, especially, have given the government much trouble. The Utes are fierce and warlike, and resist all efforts to induce them to abandon their wandering life and cultivate the soil.

Earnest attempts have been made at different periods by individuals and societies to Christianize and civilize the Indians, some of which have been remarkably successful. The French and Spanish, in connection with their colonies, had missions among the Iroquois, Chippewas, Creeks, and other tribes. In Florida, Texas, New Mexico, and California, they had prosperous missions. In 1643 Thomas Mayhew labored with success for three years at Martha's Vineyard, Mass., followed in the same work by his father, and by others of the family for five generations. In 1646 the legislature of Massachusetts passed an act for the propagation of the gospel among the Indians, and in the same year John Eliot began his labors at Nonantum, churches were formed, and the Bible and other Christian books translated. The Brainards labored with effect in New Jersey and Pennsylvania. The Moravians and Friends have been active in instructing the Indians. The various Protestant denominations, through organized societies, have had for many years missions among the Cherokees, Choctaws, Ottawas, Chickasaws, Creeks, Dacotahs, and some other tribes, instructing them not only in religion, but also in the arts of civilized life. The Indian problem, always troublesome to the U. S. government, is now seen to involve grave moral and political issues not at first recognized. The governmental policy has been one of expediency rather than justice. Treaties have been made with the tribes as with sovereign nations, but have been set aside on easy pretexts. Indians have not been considered as citizens under the law; their ownership of property, as recognized, has been tribal and not individual. They have been allowed to be the prey of rapacious speculators in land, and thievish traders. Of late years the government has sought to apply a better policy, but the evil has been found too vast and deep for easy reform; and a wave of popular feeling is now rising, bearing in upon the government with strong demands in different directions. There are signs that the discussion will result in better processes of dealing with the Indians, and that the government will find or make its way to a system that shall be wise and just. See INDIAN TERRITORY.

INDIAN SHOT, *Canna Indica*, a plant common in almost all tropical countries; a herbaceous perennial, with a creeping root-stock (*rhizome*), and a simple stem, formed by the cohering bases of the large, tough, ovate-oblong leaves. It belongs to the natural order *marantaceæ*. It derives the name Indian shot from the seed, which is hard, round, and about the size of a very small pea, and is sometimes used as shot. The seed yields a beautiful red color. The root-stocks are very large, spongy, and jointed, and are used in Brazil for emollient poultices in tumors and abscesses. The root-stocks of some of the other species of *canna* are more valuable, yielding the starch called Tous-les-mois (q.v.).

INDIAN TERRITORIES was the name formerly given to the enormous region which for the most part is now known as the NORTH-WEST TERRITORY of Canada. The north-west territory is bounded on the e. by Manitoba and Keewatin, on the s. by the United States frontier, w. by British Columbia and Alaska, and n. by the Arctic ocean. It was organized as a territory by act of the Dominion parliament in 1875, under a governor and

council of five appointed by the Dominion government. But provision is made that when any district has a population of 1000, the inhabitants shall have power to elect a member of council; and when the population becomes sufficiently numerous, the council becomes the legislature. The capital is Battleford, on the Battle river, where government buildings have been erected. Parallel to the great chain of lakes a belt of coniferous forest, 500 m. in width, extends across the whole territory. To the n. of this is the most desolate region of the earth, the home of the musk ox and summer resort of the reindeer; but the forest extends along the Mackenzie river close to the Arctic ocean. Between the forest and the U. S. frontier lies a great region of plain and prairie—a country of gently sloping hills and large treeless expanses. Along the northern portion lies the celebrated fertile belt of the Saskatchawan, stretching 800 m. from lake Winnipeg, and from 40 to 150 m. in breadth. Along with Red river valley, this is the finest wheat-growing district in the w. of America. The region between this and the American desert is of a mixed character, much of it rich soil well suited for grazing purposes, but generally deficient in rainfall. It has been estimated that the plain and prairie region covers an area of about 200,000,000 acres, of which it is believed that 80,000,000 consist of first-class soil, another 80,000,000 of mixed agricultural and grazing lands, and 40,000,000 of lakes and marshes, with dry tracts and pastures. The Indians, still the largest portion of the inhabitants, have made over their rights in the land to the government on the same conditions as throughout what was the Hudson's bay company (q.v.) territory. Settlement has begun in the e., and is proceeding rapidly from Manitoba westward. The climate is severe in winter, the thermometer falling to — 40°, but dry and clear.

INDIAN TERRITORY, a country reserved by the government of the United States for the Indian tribes removed w. of the Mississippi, and those living there. It lies between 33° 30′ and 37° n. lat., and 94° 20′ and 103° w. long., being 370 m. long by 220 wide, with an area of 74,127 sq. miles. It is bounded on the n. by Kansas, e. by Arkansas, s. and w. by Texas, from which it is separated on the s. by the Red river. It is a beautiful country, with vast fertile plains, watered by innumerable streams, including the Red river, the Arkansas, and their branches. The climate is genial, producing cotton, tobacco, maize, wheat, and fruits. Coal, iron, zinc, copper, salt, and petroleum springs abound. Its population of about 70,000 consists of Cherokees, Creeks, Seminoles, Choctaws, Chickasaws, and remnants of smaller tribes. The principal tribes are in a high state of civilization, and, except the Seminoles, all possess a written constitution and code of laws. In 1874 there were 6 high schools, and 88 day schools among the Cherokees, Choctaws, and Chickasaws. Many of the Indians cultivate large plantations.

INDIAN TERRITORY (*ante*), the home of civilized or partially civilized remnants of once powerful aboriginal tribes, removed by the government from time to time from different parts of the union, and which, upon separate reservations and under forms of government established by themselves, are living at peace with each other and with the United States. In June, 1830, congress passed an act setting apart "all that part of the United States w. of the Mississippi, and not within the states of Missouri and Louisiana or the territory of Arkansas," to be known as the Indian country. The region thus described formed a part of the Louisiana purchase of 1803 from France. Portions thereof have since been organized into new states and territories, and only a remnant of the original Indian country now remains. To it has been added, however, a narrow adjoining strip of land w. of the 100th meridian which was ceded to the United States by Texas.

The territory contains 20 reservations, the names of which, with the extent of each in sq.m., are as follows:—Arrapahoe and Cheyenne, 6,715; Cherokee, 7,861; Chickasaw, 7,267; Choctaw, 10,450; Creek, 5,024; Kansas, 154½; Kiowa and Comanche, 4,369; Modoc, 6; Osage, 2,291; Ottawa, 28½; Pawnee, 442; Peoria, 78½; Pottawatamie, 900; Quapaw, 88½; Sac and Fox, 750; Seminole, 2124½; Senaca, 81; Shawnee, 21; Wichita, 1162; Wyandotte, 38½; total area appropriated, 47,039 sq.m.; unassigned, about 22,000 sq. miles.

White speculators and adventurers have often attempted to enter the territory and appropriate the lands not included in the reservations, but the government of the United States, in fulfillment of its treaty stipulations to the Indians, has prevented them. The latest movement of this kind was made in 1879, when the president issued his proclamation warning those engaged therein to desist, and informing them that if they should enter the territory they would be expelled, if necessary, by an armed force. A bill was lately introduced in congress to erect the Indian country into a regular territory of the United States, thus opening its unsettled lands to the whites and subjecting the Indians to the very encroachments to avoid which they consented to go upon the reservations. It has been proposed in some quarters to make the Indians citizens, to place them under territorial government, and finally admit them as a state to the union. But to this plan there are some serious obstacles, not the least of which is the unwillingness of the Indians themselves to sacrince the autonomy of their respective tribes and the governments of their own already existing. Though this may ultimately be arrived at, it is not easy to see how the government of the United States could suddenly force such a change upon them without violating the most solemn treaty obligations.

The population of the territory, exclusive of white residents, is reported to number

74,140. The number of whites legally there is about 12,000, and besides them there are 5,000 others who would be excluded if the law were strictly enforced.

Agents representing the United States live among the various tribes, exercising a paternal oversight of their affairs, and protecting them from encroachments. They are appointed by the president with the consent of the senate, and, under existing regulations of the Indian bureau, are nominated by the religious denominations which have missions among the tribes. Each tribe has its own internal government, but the United States courts have jurisdiction in civil actions where a white man is a party, in cases of crime against a white man, and of violations of the laws regulating trade and intercourse with the Indians.

It appears from the report of the commissioner of Indian affairs for 1873 that there were then in the territory 217,790 acres of cultivated land, producing in that year 1,399,952 bush. of corn; 92,574 of wheat; 60,750 of oats; 198,740 of potatoes; 5,000 of barley; 6,500 of turnips; 138,745 tons of hay; 5,000 bales of cotton; and 4,000 lbs. of sugar. Furs were sold to the value of $193,560; and 3,930,468 ft. of lumber were sawed. The number of live stock was—horses, 212,155; cattle, 322,354; sheep, 13,100; swine, 430,445; total value, $9,408,187. In 1879 the number of acres of cultivated land had increased to 237,000, producing 565,400 bush. of wheat; 2,615,000 of corn; 200,500 of oats and barley; 336,700 of vegetables; and 48,353 tons of hay.

There are more than 200 common schools and ten high schools in the territory, and in the former over 6,000 children. Nearly all the tribes have abandoned their pagan religions. The traffic in ardent spirits is absolutely prohibited, and no other territory of the United States contains so many houses of worship, or so many Sunday-schools, with so numerous an attendance, as are found in this. See INDIANS, AMERICAN.

INDIAN TOBACCO. See LOBELIA, *ante*.

INDIAN YELLOW, or PURREE, is a coloring matter highly esteemed by artists. It is exported from the East Indies in masses of 3 or 4 ozs. in weight, which are of a dark brown color externally, but of a bright orange yellow in the interior. It is generally believed to be a urinary sediment of the camel or buffalo, after the animal has fed on decayed and yellow mango leaves. Its odor is peculiar, and resembles that of castoreum. This substance consists chiefly of the magnesian salts of an acid termed *purreic* or *euxanthic acid*. It is almost insoluble in cold water or alcohol, but is soluble in hot alcohol and in ether; it also dissolves freely in boiling dilute hydrochloric acid, from which stellate groups of acicular crystals of euxanthic acid ($HO,C_{42}H_{11}O_{21}$) are deposited on cooling. Alkaline solutions dissolve this acid, and form a yellow liquid. A solution of euxanthate of potash when mixed with the solutions of the salts of the earths, gives brilliant yellow, sparingly soluble precipitates, and, with acetate of lead, it forms a yellow insoluble lake.

By dry distillation, this acid yields a yellow, crystalline sublimate of *purrenone* or *euxanthone* ($C_{40}H_{12}O_{12}$), water and carbonic acid being evolved; and, with nitric acid, it yields several nitrogenous bodies of considerable interest, in a purely chemical point of view, but of no practical importance.

INDIA RUBBER. See CAOUTCHOUC.

INDICTION, a period or cycle of 15 years, the origin of which is involved in obscurity. Connecting the original meaning of the word, viz., "the imposition of a tax," with its signification in chronology, several writers have propounded theories explanatory of its origin, none of which, however, are supported by a tittle of evidence. It began to be used in reckoning time, chiefly by ecclesiastical historians, during the life of Athanasius; it was afterwards adopted by the popes, who still continue to use it, and through whose influence it came to be so generally employed during the middle ages, that the dates of charters and public deeds of this era are expressed in indictions as well as in years of the Christian era. The time from which reckoning by indictions commenced is, according to some, Sept. 15, 312; according to the Greeks of the lower empire, Sept. 1, 312; but when this method was adopted by the popes, it was ordered to be reckoned as commencing Jan. 1, 313. The latter, which is now alone used, is called the *papal indiction*. If we reckon backwards to the commencement of the Christian era, it will be seen that 1 A.D. does not correspond to the 1st, but to the 4th year of an indiction—hence, *if to any given year of the Christian era* 3 *be added, and the sum divided by* 15, *the remainder will give the position of that year in an indiction*—e.g., 1874 A.D. is the 2d year of an indiction.

INDICTMENT is the name given to the written accusation of crime against a person, and upon which he is tried by a jury. An indictment in England commences with a caption, i.e., a description of the style of the court, which, however, is no part of the indictment; then follows the venue or statement of the place where the crime was committed; next follows the accusation, which is in the name of the jurors, i.e., the grand jury. In Scotland an indictment is also the accusation on which a prisoner is tried; but it runs in the name of the lord advocate, addressed to the prisoner. In England a prisoner is not entitled, before trial, to a copy of the indictment or a list of the witnesses against him, except in treason; but he can in most cases procure a copy of the depositions of witnesses, if these were taken before a magistrate, at a trifling expense. But

many cases are not inquired into at all before a magistrate, so that this reasonable advantage is not given uniformly in England.

In Scotland, on the other hand, a prisoner is in all cases entitled to have a copy of the indictment given to him 15 days before trial, and also a list of the witnesses to be brought against him.

INDICTMENT (*ante*). In the United States persons accused of felonies or grave misdemeanors can be brought to trial only upon an indictment which a grand jury has declared to be "a true bill." When a criminal court is convened and the grand jury has been duly constituted and instructed, the state's attorney, or some other duly qualified officer, lays before them draughts of indictment against the alleged offenders, and furnishes them with the names of the witnesses whose testimony is relied upon to support the accusation. These witnesses the grand jury examines *ex parte*, not to determine the guilt or innocence of the accused, but to ascertain whether there is or is not *prima facie* evidence of guilt sufficient to warrant their trial. If twelve or more members of the grand jury pronounce in the affirmative, the presentment, with the words "a true bill" indorsed upon the back thereof, is sent to the court; and upon the charges therein contained, carefully set forth in the indictment subsequently prepared, the accused is put upon trial before a petit jury. The indictment is prefaced by a "caption," in which are set forth the name, term, and place of meeting of the court, the names of the justices, and the fact that the grand jury was lawfully constituted. Then comes a full and particular description of the alleged crime; the name of the accused must be given if known; and if not, he must be described in such a way as to make his identity sure. The time and place of the commission of the crime must also be stated, though it is not always necessary to conviction that these particulars should be exactly supported as charged. In some cases, however, a failure upon this point is fatal to the indictment. In trials for perjury the exact day when the offense was committed must be named. To prove that the crime was committed on some other day will not avail. In cases of murder the death must be described as occurring within a year and a day of the time when the alleged fatal injury was inflicted. When several persons have been concerned in the commission of a crime, they may be indicted either jointly or separately. It is usual to describe the alleged offense in different ways, in what are usually called "counts," in order to cover any uncertainty that may exist beforehand as to the precise way in which it was committed. It is enough if the prisoner is convicted upon a single count. The indictment must charge explicitly whatever is necessary to constitute the offense. In many of the states of the American union the harsh rule of the common law, which denied the right of a person accused of treason or felony to have a copy of the indictment, has been abolished by statute.

INDIES. See EAST INDIES and WEST INDIES.

INDIGES'TION, or DYSPEPSIA, is a term somewhat vaguely applied to various forms of disease of the stomach or of the small intestines in which the natural process of digesting and assimilating the food is deranged.

The symptoms of indigestion are by no means constant in all cases. There is often *anorexia* (or want of appetite), but occasionally the appetite is excessive, and even ravenous. Nausea not unfrequently comes on soon after a meal; while in other cases there is no nausea, but after the lapse of a couple of hours the food is vomited, the vomited matters being very acid, and often bitter, from the admixture of bile. In severe cases the vomiting has been known to occur after every meal for several months. Flatulence, relieving itself in eructations, is one of the standard symptoms of this affection, the gas that gives rise to this symptom being sometimes evolved from undigested matters in the stomach, and sometimes being apparently secreted by the walls of that viscus. It is very apt to occur in dyspeptic patients if they have fasted rather longer than usual. *Cardialgia* (popularly known as *heartburn*), *pyrosis* (q.v.), or water-brash, and *gastrodynia* (commonly designated *spasm* or *cramp* of the stomach, and coming on at uncertain intervals in most severe paroxysms), are other somewhat less common symptoms of indigestion.

The treatment of indigestion is more dietetic than medicinal. The quantity of food which can be dissolved by the gastric juice and intestinal fluids being limited (see DIGESTION), care should be taken that this quantity is not exceeded; moreover, the meals should not succeed each other too rapidly. Mr. Abernethy, who was a great authority on this subject, laid great stress on the principle that the stomach should have time to perform one task before another was imposed upon it, and he always recommended his patients to allow six hours to intervene between any two meals. With regard to the nature of the food best suited to dyspeptic persons, it may be safely asserted that a mixture of well-cooked animal and vegetable food is in general more easily digested than either kind taken exclusively. Mutton, fowls, and game are the most digestible kinds of animal food; and pork and all cured meats, such as salted beef, ham, tongue, etc., should be avoided. Raw vegetables, such as salads, cucumbers, etc., must also be prohibited. In most cases dyspeptic persons would probably do well to avoid all stimulating drinks; but in some cases a little cold, weak brandy and water, or a glass of old sherry, or a little bitter ale, may be taken with advantage. But upon all points of eating and drinking a sensible patient must be mainly influenced by his own experience. The unquestionable benefit which dyspeptic patients often derive from a visit to a hydropathic estab-

lishment is due perhaps not so much to any specific action of the water, as to the well-regulated diet, the withdrawal of the mind from personal cares, and the change of scene. A six weeks' or two months' tour among the mountains of Scotland or Switzerland will in the same way often do a dyspeptic patient more good than he could have experienced from any amount of physicking at home.

A few words must be said regarding the mode of treating the most urgent of the individual symptoms. Loss of appetite may be remedied by the employment of bitters, such as quinine, gentian, chiretta, etc., or of mineral acids, or of both combined. Nausea and vomiting may be treated with hydrocyanic acid, chloroform, and creasote in very small doses. Two or three drops of dilute hydrocyanic acid in an effervescent draught are often an effectual remedy. In intense vomiting, the amount of food taken at a time must be reduced to the lowest possible limit. A tablespoonful of milk, mixed with lime-water, will sometimes remain on the stomach after all other kinds of food have been rejected. There is no better remedy for flatulence than peppermint-water; if it fails, a drop of cajeput oil on a lump of sugar may be tried. When the eructations are attended with an odor of rotten eggs—that is to say, when sulphureted hydrogen is evolved from the decomposition of matters in the stomach—an emetic is the best cure. The remedies for the pain in the stomach vary with the character of the pain; bismuth, nitrate of silver, and opium are often serviceable, but should not be taken without advice. A teaspoonful of the aromatic spirit of ammonia in a wine-glass of camphor mixture often gives instantaneous relief, and if not too often resorted to, can be taken with impunity.

INDIGIR'KA, a river of Siberia, in the government of Jakutsk, rises in the Yablonoi or Stavonoi mountains, and after a northerly course, estimated at 750 m., through a frozen desert studded with a few villages, falls into the Arctic ocean in lat. 71° n., and long. 150° east.

IN'DIGO, (Gr. *Indikon*, Indian), a most important vegetable dyestuff, yielding a beautiful blue and very durable dye, the basis also of the best black dye in woolen cloths. It has been used in India from a very early period, and was imported thence by the ancient Greeks and Romans, but was lost to Europe during great part of the middle ages—although the cultivation of the plant and preparation of the dye were described by Marco Polo in the 13th c.—until reintroduced by the Dutch about the middle of the 16th century. Its use in England, France, and Saxony was then for a considerable time prevented by a strong prejudice against it, arising from the difficulty experienced in fixing the color. Since this has been overcome the cultivation of plants producing indigo, long confined to India, has extended to many other tropical and subtropical countries, as Egypt, the West Indies, Mexico, Brazil, etc. These plants generally belong to the genus *indigofera*, of the natural order *leguminosæ*, sub-order *papilionaceæ*. The keel of the corolla is furnished on both sides with an awl-shaped spur. The species of this genus number at least 150, and are natives of almost all tropical and subtropical countries. Of these, *I. tinctoria* is the species most generally cultivated in India. It is a half-shrubby plant, 2 to 3 ft. high, with pinnate leaves, which have five or six pair of long-obovate, dull, bluish-green leaflets, and racemes of axillary pale red flowers.

The province of Tinnevelly produces a great quantity of indigo. Bengal produces, on an average, about nine millions of pounds annually. The sum which Europe annually pays for indigo is estimated at eight or ten millions of pounds sterling.

Indigo is, however, obtained from plants of other genera, particularly from *Wrightia tinctoria* (natural order *apocynaceæ*), East Indies; *baptisia tinctoria* (natural order *leguminosæ*), North America, which yields indigo of a pale color and very inferior quality; *tephrosia tinctoria* (natural order *leguminosæ*), Malabar; and *T. Apollinea*, Egypt and Nubia; *marsdenia tinctoria* (natural order *asclepiadaceæ*), in Sylhet; and *polygonum tinctorium* and *P. chinense* (natural order *polygonaceæ*), China and Japan. *Wrightia tinctoria* is a large shrub, indigenous to great part of India and to Ceylon, yielding indigo of the finest quality, and is recommended by Dr. Roxburgh for cultivation, as less dependent than the common indigo plants on rain and irrigation. It grows very freely, and throws out shoots rapidly on their being cut away.—In times when East Indian indigo was not known, or was brought to Europe only in small quantity, the same dyestuff was obtained from woad (q.v.).—A coarse kind of indigo, called bastard indigo, was also at one time made in North America from the young shoots of *amorpha cærulea*.

The Manufacture and Applications of Indigo.—The indigo plant, in its general appearance, is not unlike the lucerne of our fields. The seed is sown in drills about 10 in. apart, and soon makes its appearance above ground, when it requires incessant care to keep the weeds down, which otherwise would soon choke so tender a crop. In about three months the plants begin to flower, and are then cut down, but soon shoot up again, and yield a second cutting, sometimes a third, the same year. Formerly, indigo was carefully dried after being cut, and even fire-heat was sometimes used for the purpose, but now—at least in India—the practice is abandoned, and it is found in every respect better to use the plant whilst fresh and green. The first process is to pack a large vat full of the freshly cut indigo; heavy wooden beams are placed on the top to press it and fix it down; and water is then let into the vat, enough just to cover it. Being left in this state for from 10 to 12 hours, fermentation is set up, and much gas disengaged, the water becoming a light-green color. The green liquor is then run off into the second

vat, which is placed below the level of the first, in which, whilst the fermentation process is being repeated upon a fresh supply in the first vat, it is violently agitated by being beaten with poles: this causes the *grain*, as it is called, to separate, and the green matter suspended in the liquor becomes blue and granular. When this operation is sufficiently advanced the contents of the vat are allowed to settle, and the sediment is then run into the third vat, which is below the level of the second; from which it is pumped into a boiler. The boiler is slightly heated, and then allowed to stand for a few hours, during which time the indigo settles down, and as much clear water as possible is drawn off from above it. The boiler is then again heated, and this time up to the boiling-point; after which its contents are allowed to run on to a frame of wood, lined with "long-cloth" sheeting, where they remain to drain till about the consistence of very thick cream, when they are removed, and subjected to very heavy screw pressure; and when as hard and dry as ordinary soap, are cut by brass wire on a frame into cubes about 3 in. square; and these are laid out, so as not to touch each other, on the shelves of the drying-house. Finally the cakes are cleaned, one by one, and tightly packed in boxes for the market.

This dye is, without doubt, the oldest in use; the Greeks and Romans obtained a knowledge of its uses from India, where its employment has been very general for a great length of time. Much obscurity involves indigo and its early use, in consequence of the variation in its name; for instance, the Tamools of India call the plant *averie* and the dye itself *neelum;* in Sanskrit, the plant is *vishashodanie*, and the dye *nīlī* and *nīlinī*, whence the *anil* of the Portuguese. The Malays call the dye *taroom*, and the Arabs, *neel*.

Commercially speaking, indigo may be said to be the produce of India and Central America, as these are the only localities which supply the recognized form of the article. In India, the chief seat of the indigo manufacture, Bengal is the most important district. The total quantity received in Great Britain in 1876 was upwards of 88,000 cwts.—a vast quantity, when it is borne in mind with what difficulty it is cultivated and manufactured. When pure, indigo has a rich, dark-blue color, almost purple; it is in small cubes or parts of cubes, and its fracture shows a tendency to break up into square pieces, and indicates cracks in its substance, often filled up with a film of whitish efflorescence, probably the lime used in precipitating it. It has neither taste nor smell, and its specific gravity is about 1.50; if rubbed with any hard substance, it gives a streak with a bright coppery luster. The varieties recognized in commerce are—1st, Bengal, which, from the care taken in its preparation, and the large scale on which it is made in that district, is the best; and its various gradations of quality, ten in number, varying from 9s. to 5s. per lb., are always kept distinct. In other sorts they are usually much mixed. 2d, Madras and Kurpah; 3d, Oude; 4th, Manila; 5th, Java; and 6th, South America. The last is packed in serons or cases of dried ox-skin, and its qualities are distinguished as follows: 1st, flores; 2d, sobres, and 3d, cortes; all the others are in wooden chests, containing about 250 lbs. each.

Few materials are of greater importance to the dyer than indigo, and none require the exercise of more care and skill in using. Being insoluble in water, it requires the action of other solvents to render it capable of penetrating the fibers of the materials to be dyed. The method generally employed is the following: The indigo is broken into small lumps, and these are soaked in hot water, and left for at least 48 hours, in order that the moisture may soak through and soften them; after which they are put into the indigo-mill, which is a levigating machine, consisting of a vessel in which a roller is made to work by machinery, so as to rub down the indigo, mixed with plenty of water, to a very fine paste. This is a tedious operation; therefore, in large establishments there are usually numerous mills in the grinding-room. When sufficiently ground, the paste is removed to the dyeing-vat, where to one part of indigo is added one part of lime and three-fourths of sulphate of copper; these are well mixed with sufficient water to fill the vat, and the dyer then proceeds to dye either cotton, linen, or silk goods. See DYEING. After being dyed, the goods are dipped into a bath of diluted sulphuric or hydrochloric acid, which gives brightness and purity to the color; they are then finished by washing in a stream of pure water, and drying.

Green indigo, called *lo-kao* by the Chinese, is a substance resembling indigo, which is obtained from a tree called *hom-bi;* it is highly valued by the Chinese artists as a pigment, and also gives a beautiful permanent green color to cotton and silk cloths; it is, however, so costly, that it never can, unless differently prepared, be used as a dyeing material. The fact that the Chinese dye cotton cloths with it, is accounted for by the nature of the process of preparing the lo-kao, which is this: A well-macerated decoction of the bark of the hom-bi tree is largely diluted with water mixed with a little lime; pieces of cotton cloth are then dipped into the vat, and taken out and exposed to the sun, which changes them to a bright green; they are then placed in perfectly clean water, and agitated until the water has removed all the free coloring matter; this water is then evaporated, and the small sediment left is the lo-kao. It is the cotton cloths thus used that are sold as green-dyed goods. It is said that a similar dye stuff is obtained from another tree called *pa-bi*, and although this, as made by the natives, is much too costly to use in European dyeing, yet probably, if better means of obtaining it can be pointed out, it may become an important article of commerce.

Chemistry of Indigo.—The plants which yield indigo present no indication, when

growing, that they contain any *chromogen*, or matter capable of yielding pigment, nor is it definitely known in what form the indigo exists in the vegetable tissues.

The indigo of commerce is by no means a homogeneous body. Its essential and most important constituent is *indigotin*, or *indigo blue*, but it likewise contains *indigo brown*, *indigo red*, and other ingredients.

Indigo blue, or *indigotin* ($C_{16}H_5NO_2$), is obtained from commercial indigo by extracting the ingredients with which it is mixed by acetic acid, alkalies, and boiling alcohol. It occurs either as a dark-blue amorphous powder, or in purple, crystalline scales, with a metallic luster. It is devoid of smell and taste, and is insoluble in water, alcohol, ether, dilute acids, and alkalies. When carefully heated, it may be sublimed without decomposition. Among the products of its destructive distillation are hydrocyanate and carbonate of ammonia, aniline, etc. Indigo blue dissolves without any evolution of gas in strong sulphuric acid, forming a blue solution of *sulphindigotic acid*, which is extensively used for dyeing cloth, under the name of *Saxony blue*.

Under the action of reducing agents, such as alkaline fluids containing sulphate of iron, or a mixture of grape-sugar, alcohol, and strong soda lye, indigo blue becomes converted into *indigo white* or *reduced indigo*, which forms a yellow solution in alkaline fluids, but which, on free exposure to the air, absorbs oxygen, and is reconverted into indigo blue. Indeed, this is the best method of obtaining the latter in a state of purity from commercial indigo, of which it should form about 50 per cent.

Indigo blue occurs in small quantity in the urine of man, the horse, and the cow, and occasionally in the milk of the cow, when these fluids have been exposed for some time to the action of the air; but Schunck obtained it from the urine in so many cases (in the urine of 39 persons out of 40), that indican (or the cromogen-yielding indigo blue) must be regarded as a normal urinary constituent. See M. Schunck's paper in *The Memoirs of the Literary and Philosophical Society of Manchester*, 1857, vol. xiv., or Day's *Chemistry in its Relations to Physiology and Medicine*, 1860, pp. 310–12.

Indigo white or *reduced indigo*, in a state of purity, occurs in white flakes, which are devoid of taste or smell, are perfectly neutral, and are insoluble in water, but dissolve in alcohol, ether, and alkaline solutions. Its composition is represented by the formula $C_{16}H_6NO_2$, and as it only differs from indigo blue, $C_{16}H_5NO_2$, in containing one more equivalent of H, it may be considered as the hydride of the latter. If yarn or woven goods be immersed in an alkaline solution of this substance till they are thoroughly saturated, and are then exposed to the air, indigo blue is formed within the fibers of the tissue. The blue dye thus obtained is very intense and permanent. From its property of becoming blue on exposure to the air, indigo white is a sensitive test for the presence of free oxygen.

Many compounds of great chemical interest have been derived from indigo blue. It was from indigo that aniline (now so largely employed in the production of the pigments known as *mauve* and *magenta*) was first obtained.

INDIGO BIRD, *Cyanospiza cyanea*, a North American bird of the finch family (*fringillidæ*), a native of the United States, as far n. as the Missouri, which it visits in summer, and of Central America, where it spends the winter. It is about 5½ in. in length, of a beautiful blue color, variously tinged and shaded, the lores and angles of the chin velvet black. It frequents open places on the edges of woods, and delights to sit singing on the top of a high tree. Its song is very sweet. It is easily domesticated, and is much in request as a cage-bird.

INDIUM, a metal discovered in 1863 by spectrum analysis, in the zinc blende of Freiberg, by Richter and Reich. It is named from two indigo-colored lines in the spectrum. It has also been found in the black blende of Saxony (christophite), in the wolfram of Linnwald, and in blende of Maine. It may be prepared from crude metallic zinc, or from the deposits in galvanic batteries, by dissolving them in nitric acid and treating the filtrate with ammonia, which precipitates the oxide of indium; this is reduced to the metallic state by hydrogen or potassium cyanide. Indium has a sp. gr. of 7.421. Its atomic weight is 113.4. Its melting point is 349° F. It is not easily oxidized, even above the point of fusion. The pure metal has a bluish silvery luster somewhat like lead, which it also resembles in softness and ductility. The principal compounds have the following formula:

Chloride	$InCl_3$.
Yellow oxide	In_2O_3.
Hydroxide	InH_3O_3.
Nitrate	$In3NO_3$.
Sulphate	$In_23SO_4+9H_2O$.

INDIVIDUALITY, the quality of being individual: separate or distinct existence. There is some difference of opinion as to what constitutes individuality, the discussion being principally confined to the domain of natural history. Some authorities regard the various organisms springing by buds from a single hydroid as an individual. Others again consider various parts of a tree to be individuals. The question cannot be settled without looking at it from two points of view. In one sense all the organisms proceeding from one egg may be considered as comprising one individual, being derived from

one germ, the production of the zoöids by budding being similar to the development of a stock by grafting; but similar only because, in grafting, a part of one individual, and not a germinal part, is inserted into another, and there proceeds to grow, as though the original plant extended itself. But in the budding of hydroids the different zoöids thus produced exactly resemble each other, depart from each other, and develop independently into hydroids like their parent; and some may develop much more rapidly than others. The production of a zoöid is more like original germination or ovum development than the growth and extension of a part of the common tissues of a parent. In one sense the new tree which has grown from the stock of another is a part of that tree; but in another, and probably a more exact sense, it is another and entirely independent tree—a separate individual. A tree, taken as a whole, whether while putting out its leaves, or in bloom, or bearing ripe seed, is an individual, while each ripe seed may be regarded as potentially an individual. If it fall upon the earth and sprout it becomes an individual tree, like its parent. It might be said that the acorn does not become an individual in a strict sense until it becomes a tree; but it may be held logical to consider that it became an individual as soon as it became a perfectly developed seed. If we do not look at the subject in this way we shall be obliged to regard all objects in nature as mere fragments of one great whole, which in a spiritual sense is true; but the application of metaphysical methods to natural science only leads to confusion. Each leaf of a plant is certainly an individual leaf, but in a true sense it is not an individual, for it can have no independent existence; it is only a part of a compound organ of respiration of plant life, and may be compared to a pulmonary vesicle of the lung of an animal.

In the case of the Siamese twins, they are, doubtless, correctly regarded as two individuals, and yet in so far as their livers, which seem to have been united, were really combined and performed their functions in union, they were not quite distinct individuals. They must have possessed individual minds, and, in the higher sense, were entirely distinct individuals. Other monsters have been born having two heads and only one body. It would not be logical to regard such, taken as a whole, as being distinct individuals, each brain being dependent upon a common body. In one sense the organism comprises two individuals, but in another it does not. If such a monster could live, the two brains could not be independent in function of each other. Individuality is, therefore, to a certain degree, a relative term, and the use of the term sometimes requires explanation. This is one of those questions in which is illustrated the dependence of physical upon metaphysical science.

INDIVISIBLES, in mathematics. According to the theory of indivisibles, volumes are composed of an infinite number of planes, planes of an infinite number of lines, and lines of an infinite number of points. The point, then, is the indivisible element to which all magnitudes can be reduced—the atom of mathematics. By the method of indivisibles, as developed by geometricians of the middle ages, some of the problems to which the method of infinitesimals is now applicable were successfully solved.

INDO-CHINA (FARTHER INDIA), or the INDO-CHINESE PENINSULA. See SIAM, BURMAH, COCHIN-CHINA, *ante*.

INDO-GERMANIC LANGUAGES. See ARYAN LANGUAGES.

INDORE', a Mahratta principality of Hindustan, consists of several detached tracts, some of them lying very remote from each other. With an aggregate area of 8,075 sq.m., and an aggregate population of about 640,000, the territory, as a whole, is traversed from e. to w. by the Nerbudda, and also by the Vindhya mountains, their loftiest point within its limits being 2,500 ft. above the sea. The revenue is nearly a quarter of a million sterling; and the armed force amounts to about 20,000 men. Besides the capital, the chief towns are Rampûra, Mehadpore, Dhi, Pitlaud, Mundlaisir, Bhanpûra, and Mhow. Indore is peculiarly the country of the Bheels, one of the wildest and most savage of the aboriginal tribes of India. The country, including all between its extremes, stretches in n. lat. from 21° 18′ to 24° 46′, and in e. long. from 74° 39′ to 76° 26′. The climate is sultry, the thermometer ranging from 60° to 90° F. in the shade.

INDORE, the capital of the principality of the same name, is situated in 22° 42′ n., and long. 75° 50′ e., on the left bank of the Kuthi It stands about 2,000 ft. above the level of the sea, and is estimated to contain 15,000 inhabitants. This place, mean and insignificant enough in itself, acquired considerable notoriety in connection with the grand revolt of 1857. Though Holkar, the rajah, remained faithful to the British government, yet his troops mutinied on July 1, holding their prince as a prisoner in his own palace, and butchering many Europeans, men, women, and children, in cold blood. Indore is of modern erection, having been founded in 1767; and its original namesake, now Jemnah, still exists on the opposite bank of the river.

INDORSED, ENDORSED, or ADDORSED, terms applied in heraldry to two animals placed back to back. Two keys, two wings, etc., may also be indorsed, and a pelican is always drawn with his wings indorsed.

INDORSEMENT, the term generally used to denote the writing of the name of the holder on the back of a bill of exchange or promissory note, on transferring or assigning it to another. Signing the name "A. B." alone is a blank indorsement; and if the

transferee is named it is a special indorsement. The usual form is: "Pay C. D. or order. (Signed) A. B." In Scotland it is: "Pay the contents to C. D. or order. (Signed) A. B." When personal liability is to be avoided, the words "without recourse" are added. The word indorsement is also frequently used in English law, to denote any matters written or indorsed on the back of writs or deeds, as indorsements on declarations, on writs of summons, etc.

INDOSTAN. See INDIA, *ante*.

INDRA (from the Sanskrit *id*, which probably meant "to see, to discover," hence literally, "he who sees or discovers," scil., the doings of the world) is the name of one of those Hindu deities that were worshiped more especially in the Vedic period of the Hindu religion, but enjoyed a great legendary popularity also in the Epic and Purânic periods. See INDIA, sect. *Religion*. In that class of Rig-Veda hymns which there is reason to look upon as the oldest portion of Vedic poetry, the character of Indra is that of a mighty ruler of the bright firmament, and his principal feat is that of conquering the demon *Vritra*, a symbolical personification of the cloud which obstructs the clearness of the sky, and withholds the fructifying rain from the earth. In his battles with Vritra, he is therefore described as "opening the receptacles of the waters," as "cleaving the cloud" with his "far-whirling thunderbolt," as "casting the waters down to earth," and "restoring the sun to the sky." He is, in consequence, "the upholder of heaven, earth, and firmament," and the god "who has engendered the sun and the dawn." And since the atmospherical phenomena personified in this conception are ever and ever recurring, he is "undecaying" and "ever youthful." All the wonderful deeds of Indra, however, are performed by him merely for the benefit of the good, which in the language of the Veda means the pious men who worship him in their songs, and invigorate him with the offerings of the juice of the soma plant. See INDIA, sect. *Religion*. He is therefore the "lord of the virtuous," and the "discomfiter of those who neglect religious rites." Many other epithets, which we have not space to enumerate, illustrate the same conception. It is on account of the paramount influence which the deeds of Indra exercise on the material happiness of man, that this deity occupies a foremost rank in the Vedic worship, and that a greater number of invocations are addressed to him than to any other of the gods. But to understand the gradual expansion of his mythical character, and his ultimate degradation to an inferior position in the Hindu pantheon of a later period, it is necessary to bear in mind that, however much the Vedic poets call Indra the protector of the pious and virtuous, he is in their songs essentially a warlike god, and gradually endowed by imagination, not only with the qualities of a mighty, but also of a self-willed king. The legends which represent him in this light seem, it is true, to belong to a later class of the Rig-Veda hymns, but they show that the original conception of Indra excluded from his nature those ethical considerations which in time changed the pantheon of elementary gods into one of a different stamp. Whether the idea of an incarnation of the deity, which, at the Epic and Purânic periods, played so important a part in the history of Vishnu, did not exercise its influence as early as the composition of some of the Vedic hymns in honor of Indra, may at least be matter of doubt. He is, for instance, frequently invoked as the destroyer of cities—of seven, of ninety-nine, even of a hundred cities—and he is not only repeatedly called the slayer of the hostile tribes which surrounded the Aryan Hindus, but some of the chiefs slain by him are enumerated by name. The commentators, of course, turn those "robbers" and their "chiefs" into demons, and their cities into celestial abodes; but as it is improbable that all these names should be nothing but personifications of clouds destroyed by the thunderbolt of Indra, it is, to say the least, questionable whether events in the early history of India may not have been associated with the deeds of Indra himself, in like manner as, at the Epic period, mortal heroes were looked upon as incarnations of Vishnu, and mortal deeds transformed into exploits of this god.

The purely kingly character of Indra assumes its typical shape in the *Aitareya-Brâhmana*, where his installation as lord of the inferior gods is described with much mystical detail; and from that time he continues to be the supreme lord of the minor gods, and the type of a mortal king. During the Epic and Purânic periods, where ethical conceptions of the divine powers prevail over ideas based on elementary impressions, Indra ceases to enjoy the worship he had acquired at the Vedic time, and his existence is chiefly upheld by the poets, who, in their turn, however, work it out in the most fantastical detail. Of the eight guardians of the world, he is then the one who presides over the east, and he is still the god who sends rain and wields the thunderbolt; but poetry is more engrossed by the beauty of his paradise, *Svarga*, the happy abode of the inferior gods, and of those pious men who attain it after death in consequence of having, during life, properly discharged their religious duties; by the charms of his heavenly nymphs, the *Apsarasas*, who now and then descend to earth, to disturb the equanimity of austere penitents; by the musical performances of his choristers, the *Gandharvas;* by the splendor of his capital, *Amarâvatî;* by the fabulous beauty of his garden, *Nandana*, etc. A remarkable trait in this legendary life of Indra is the series of his conflicts with Krishna, an incarnation of Vishnu, which end, however, in his becoming reconciled with the more important god. As the god who is emphatically called the

god of the hundred sacrifices (*Satakratu*), Indra is jealous of every mortal who may have the presumption of aiming at the performance of that number of sacrifices, for the accomplishment of such an intention would raise the sacrificer to a rank equal to that which he occupies. He is therefore ever at hand to disturb sacrificial acts which may expose him to the danger of having his power shared by another Indra. According to the Purânas, the reign of this god Indra, who is frequently also called *Sakra*, or the mighty, does not last longer than the first *manwantara*, or mundane epoch. After each successive destruction of the world, a new Indra was created, together with other gods, saints, and mortal beings. Thus, the Indra of the second manwantara is *Vipaschit;* of the third, *Susânti;* of the fourth, *Sivi;* of the fifth, *Vibhu;* of the sixth, *Manojava;* and the Indra of the present age is *Purandara.* When represented in works of art, Indra is generally seen riding on his elephant; and where he is painted he is covered with eyes.

INDRÂNI', a name of the wife of the Hindu god Indra (q.v.).

INDRE, a central department of France, formed out of the western portion of the old province of Berri, lies immediately s. of the department of Loir-et-Cher. Area 2,620 sq.m., of which about four-fifths are in tillage and pasture. Pop. '76, 281,248. The department is well watered, the chief rivers being the Indre, the Creuse, and its tributary, the Anglin. The surface is for the most part flat, and the land is generally fertile, producing large crops of wheat and barley. The two principal resources of the department, however, are its vineyards and its flocks. The climate, except in the district of La Brenne, is mild and healthy. The principal manufactures are woolen and linen cloths, hosiery, scythes, paper, and porcelain. Iron mines are worked. The department is divided into four arrondissements—Châteauroux, Le Blanc, Issoudun, and La Châtre. The capital is Châteauroux.

INDRE, a river of France, rises on the northern border of the department of Creuse, flows n.w. through the departments of Indre and Indre-et-Loire, and joins the Loire 17 m. below Tours, after a course of 136 m., for the last 40 of which it is navigable.

INDRE-ET-LOIRE, an inland department of France, formed out of the ancient province of Touraine, lies n.w. of the department of Indre. Area 2,350 sq.m., of which more than one half is arable; pop. '76, 324,875. The department is watered by the Loire, the chief river, and by its tributaries, the Cher, the Indre, and the Vienne, all of them navigable. The Loire, to prevent inundations, which otherwise would be frequent and disastrous, is banked in by dikes throughout its course in this department. See LOIRE. In the s., the surface is hilly, and either waste or wooded, but in the other districts it is undulating or flat, and very fertile. Of the products, which include an abundant yield of the ordinary breadstuffs, wine, of which about 14,000,000 gallons are made in ordinary years, is one of the most important. The chief manufactures are bar-iron, powder, files, woolen cloth, silk, and leather. The department is divided into the three arrondissements of Tours, Chinon, and Loches; capital, Tours.

INDRIS. See LEMUR, *ante.*

INDU'CIÆ LEGA'LES, in Scotch law, means the number of days which a defender has to answer a summons. The term is not used in England, the phrase being "so many days to answer, to plead, etc."

INDUCT, the power of presenting to benefices, granted by the church of Rome to kings and cardinals. When the pragmatic sanction was abolished, 1516, Francis I. of France received the power of nominating to the bishoprics within his realm. The college of cardinals, by an agreement with Paul IV., 1555, have the disposal of the benefices which depend on them.

INDUCTION of clergyman, a term used in England and Ireland to denote the investing or giving possession of a benefice to a clergyman. In England and Ireland this is done by a mandate from the bishop to the archdeacon or corresponding official to make the induction. The inductor takes the clergyman by the hand, and lays it on the ring-key or latch of the church-door, then opens the door and puts him into the church, and generally the church bell is tolled, to give notice to the parishioners. In Scotland, the presbytery induct the minister.

INDUCTION, the name for one of the great processes of scientific discovery and proof. It has been seen under GENERALIZATION, that when we rise from particular facts to generalities, the result may take one of two forms—a general *notion*, or a general *proposition:* "circle" is a notion; "the circle is the line that incloses the largest space," is a proposition. The mode of arriving at such general affirmations, truths, or laws, is what is called induction. The strict meaning of the term is "the operation of *discovering* and *proving* general propositions;" while deduction, on the other hand, is the method of *applying* general propositions once discovered to particular cases, considered to be included within their scope. By induction we establish the law that heat expands bodies; by deduction we apply it to explain why a clock is slower in summer than in winter, owing to the changes of the length of the pendulum.

Induction is the only process of real inference—in other words, by it we proceed

from the known to the unknown; or from a limited range of facts, we affirm what will hold in an unlimited range. All things that we do not know by actual trial or ocular demonstration, we know by an inductive operation. Deduction is not real inference in this sense, since the general proposition already covers the case that we apply it to; in a proper deduction, the conclusion is more limited than the premises. By the inductive method, we obtain a conclusion much larger than the premises; we adventure into the sphere of the unknown, and pronounce upon what we have not yet seen. This operation necessarily implies a certain hazard; and it may be easily supposed that there are precautions requisite in working it. Nothing is more common than the making of bad inductions; and accordingly it is now considered a part of logic to lay down the rules for the right performance of this great operation.

A preliminary question arises—How can we ever be entitled to dogmatise beyond the sphere of our actual experience; to conclude, for instance, that five miles below the surface of the earth there is heat enough to make water boil? The answer to this question supplies us with what is called the *ground of induction*, which is the fact, now established by the experience of centuries, *that nature is uniform*. What has happened once, will happen again, provided the same circumstances and situation of things are exactly repeated. At a former period of the world's history, there might have been doubts on this matter, and opinions were actually held that implied a want of perfect uniformity, but now those doubts are dispelled, except, perhaps, with reference to a single question—viz., the freedom of the will (see FREE WILL). Accordingly, the problem to be solved is to ascertain what is the order of nature in the instances accessible to our observation.

The uniformity of nature is a compound of many separate uniformities. In other words, there are different departments or classes of phenomena, each determined by separate laws. Thus, we have mathematical, physical, chemical, physiological laws, the statement of which severally constitutes the subject-matter of each of these sciences. Now, a distinction is observable, which is of some importance as regards the method of inductive investigation, Some of the phenomena thus conjoined under uniform principles are properties *simultaneously* existing, as the properties of mathematical figures; others are *successions*, and affirm order in time, the most important of all which is that peculiar succession denominated cause and effect. See CAUSE. The problem of inductive inquiry is in a great measure occupied with this one department, although there are also inductions respecting contemporaneous or conjoined properties. Natural history is in part made up of affirmations of simultaneous properties, as, for example, the anatomical structure of animals, and in part of affirmations of cause and effect, as in all the operations that sustain life, and determine reproduction, growth, and death.

Respecting the whole of the phenomena implied under causation, the principle of nature's uniformity is embodied in one great and comprehensive statement, called the law of causation; the import of which is, that whatever begins to exist is uniformly preceded by something else, to which it invariably succeeds. Events do not arise of themselves, or out of nothing; and although there is such a thing as plurality of causes, everything that arises is preceded by some other thing as a cause, and always follows when that cause occurs; there being supposed no counteracting agency. The aim of the scientific inquirer, then, is to single out from the mass of circumstances that have accompanied and preceded any event, some one or more that invariably precede the occurrence of that event, which being found, are thenceforth known as its cause. This has to be accomplished by a process technically called *elimination*, by which is understood a series of operations intended to separate everything that is indifferent to the production of the phenomenon, until we arrive at some one thing or more that cannot be removed without making the effect to cease.

Mr. John Stuart Mill, in his *Logic*, has illustrated in detail the methods to be adopted for making sure that we have singled out the true causative circumstance from among the many that may precede a given effect. They resolve themselves mainly into two. "One is, by comparing together different instances in which the phenomenon occurs. The other is, by comparing instances in which the phenomenon does occur, with instances *in other respects similar* in which it does not. These two methods may be respectively denominated the method of agreement, and the method of difference."

The method of agreement supposes that we make it a study to *vary the circumstances* under which the supposed phenomenon is produced. Either by observation of cases presented in nature, or by artificially contriving new cases, in other words, by experiment, we do our utmost to obtain the effect in a great many different connections, whereby we ascertain what things are indifferent to it. Whatever circumstance can be excluded, the phenomenon still happening, or can be absent notwithstanding its presence, is not connected with it in the way of causation. The accidental or indifferent circumstances being thus eliminated, if only one remains, that is the cause; if the elimination does not go so far, but leaves three or four circumstances or agents, we can only say that the cause is among them. Mr. Mill enunciates the method of agreement in a formal canon, or rule of induction, to the following effect: *If two or more instances of the phenomenon under investigation have only one circumstance in common, the circumstance in which alone all the instances agree is the cause (or effect) of the given phenomenon.*

If we could always obtain the requisite variety of circumstances for the exclusion of

all indifferent adjuncts, this method would fully answer the ends of inductive inquiry. But this is not always to be had, and even when practicable, the operation is often very laborious. When the other method (difference) can be applied, the desired end is reached by a shorter route. If, instead of excluding the indifferent agencies one by one, we can contrive an experiment, or make an observation, that excludes *one* agency or circumstance, followed by the cessation of the effect, we conclude at once that what has thus been left out is the cause, or an essential condition or part of the cause. Whenever we are so fortunate as to light upon two instances suited to this method, we establish causation at once and beyond all question. The *experimentum crucis* of Bacon was something of this nature; only it supposed that a question lay between two alternative or competing agencies, which an experiment had been hit upon for deciding; such an experiment behooved to be one of difference. This method is embodied in the following canon: *If an instance in which the phenomenon under investigation occurs, and an instance in which it does not occur, have every circumstance, except one, in common, that one occurring only in the former, the circumstance in which alone the two instances differ is the effect, or cause, or a necessary part of the cause, of the phenomenon.*

These are the two leading methods, but there are certain cases met by a procedure somewhat different. Sometimes we have a phenomenon made up of causes partly known and partly unknown. It is then possible to subduct the effects due to the known causes, and what remains will be attributed to the remaining agencies. This is expressed by Mr. Mill in the following rule or canon: *Subduct from any phenomenon such part as is known by previous induction to be the effect of certain antecedents, and the residue of the phenomenon is the effect of the remaining antecedents.* The more our knowledge is extended, the more able are we to proceed upon this method, termed the method of residues. "It is by this process, in fact," says sir John Herschel, "that science in its present advanced state is chiefly promoted."

There remains a class of laws wherein the application of any of those three methods is rendered impracticable, from the circumstance that the agency in their case is irremovable and indestructible, so that we cannot obtain any cases where it is entirely absent. Such an agent is heat, which can never be entirely separated from any body, so as to ascertain, by comparing cases of its presence with those of its absence, what effects are due to it. So we can never get out of the sphere of the earth's attraction. The difficulty hence arising is surmounted by observing the *variations of degree* of the cause, and whether there be a corresponding variation in the degree of the effect. Thus, we infer that heat is the cause of the expansion of bodies, and that its total absence would lead to their maximum condensation and consolidation, by watching the effects of any additions or subtractions of a body's temperature. Solids, liquids, and gases (with certain limited and special exceptions) are found expanding steadily as they are heated, and contracting as they are cooled; and this is to us a sufficient justification for considering that the law in question holds good. This process is termed by Mr. Mill the method of concomitant variations, and is expressed by him in the following terms: *Whatever phenomenon varies in any manner whenever another phenomenon varies in some particular manner, is either a cause or an effect of that phenomenon, or is connected with it through some fact of causation.*

There are many problems growing out of the applications of induction to the great variety of natural phenomena, the main principles being nevertheless the same. An important extension of the means of scientific discovery and proof arises after a certain number of general laws have been discovered, and when phenomena can be shown to be results of the operation of one or more of such laws. Thus, the great induction of universal gravity was applied *deductively* to explain a great many facts besides those that enabled the induction to be made. Not merely the motions of the planets about the sun, and the satellites about the planets, but the remote and previously unexplained phenomena of the tides, the precession of the equinoxes, etc., were found to be inferences from the general principle. This mode of determining causes is called the deductive method. When several agents unite in a compound effect, there is required a process of calculation to find from the effects of the causes acting separately the combined effect due to their concurrent action, as when the path of a projectile is deduced from the laws of gravity and of projectile force. It is the deductive stage of science that enables mathematical calculation to be brought into play with such remarkable success as is seen in astronomy, mechanics, etc. See DEDUCTION.

The circumstance that phenomena may result from a concurrence of causes, leads to the distinction between ultimate laws and derivative or subordinate laws. Thus, gravity is an ultimate law; the movement of the planets in ellipses is but a subordinate law. These inferior laws may be perfectly true within their own limits, but not necessarily beyond certain limits, of time, place, and circumstance. A different adjustment of the two forces that determine a planet's motion, would cause a circular or a parabolic orbit; and therefore it is, that when phenomena result from a combination of ultimate laws acting under a certain arrangement, they are not to be generalized beyond the sphere where that arrangement holds. These inferior laws are sometimes mere inductions that have not been resolved into their constituent laws, and then they go under the name of "empirical laws." Thus, in the hands of Kepler, the elliptic orbit of the planets was only an empirical generalization, ascertained by the method of agreement;

Newton converted it into a derivative law, when he showed that it resulted from the more general laws of gravity, etc. The earlier stages of induction present us with many of those empirical laws; in some subjects—as physiology, medicine, etc.—the greater number of inductions are of this character. The cure of disease is especially an example of this: hardly any medicine can have its efficacy traced to ultimate laws of the human system. Hence the uncertainty attending the application of remedies to new cases, and also the want of success that often attends them in circumstances where we think they ought to succeed.

Induction applies to other laws than those of causation—namely, to uniformities of co-existence. For the illustration of these, as well as the other parts of induction, see Mill's *Logic*, book iv.

INDUCTION OF ELECTRIC CURRENTS. The discovery of the power of electric currents to induce currents in neighboring conducting circuits is due to Faraday. His researches on the subject, named by him *volta-electric* induction, were published in the Philosophical Transactions (1831–32). Henry (1832) observed that when contact was broken in a long galvanic circuit a bright spark occurred, which did not occur when the circuit was short. This was shown by Faraday (1834) to be due to the extra current induced by the various parts of the circuit in each other. Bachhoffner and Sturgeon (1837) showed the superior action, in induction apparatus, of a bundle of iron wires to that of a solid bar of iron. Henry (1841) studied the inductive action of induced currents of different orders. De la Rive designed, in 1843, an electro-chemical condenser, consisting of a primary coil, which, by means of the extra current, could enable a single galvanic cell to decompose water. The same decomposition, however, had been effected by Wright in 1840. Ruhmkorff constructed (1850 or 1851) the first so-called *induction coil*, the excellence of which was chiefly attained by the proper insulation of the secondary coil. Fizeau (1853) increased immensely the power of the coil, by providing it with a condenser. Of late years coils of great power have been constructed, rivaling, if not exceeding, the most powerful electric machines in length and power of spark.

The fundamental law of current induction may be thus shown: Two long copper wires are fixed so as to be parallel and close to each other. The extremities of the one are in connection with the poles of a galvanic battery, and those of the other, with the binding-screws of a galvanometer. The instant the circuit of the battery is completed, and the current sent along one wire, a current in the opposite direction is induced in the other wire, which is shown by the deflection of the needle of the galvanometer. This induced current is only momentary, for though the current continues to circulate in the first wire, the needle soon falls back to its original position of rest, and the wire then gives free passage to other currents, and appears to be in no way affected. If, now, when the needle is at rest, the battery circuit be broken, and the current stopped, another momentary current is indicated by the galvanometer needle, but in this case in the same direction as the inducing current. The inducing wire and current are called *primary*, and are so distinguished from the induced wire and current, which are termed *secondary*. The passive condition of the wire while thus under induction has been described by Faraday as electro-tonic. An electric throb, so to speak, marks the setting in of this state, and another its vanishing; the former in the opposite direction to that of the inducing current, and the latter in the same direction. If the primary wire be movable, so that it can be suddenly brought near to, and withdrawn from the secondary, while the battery current passes steadily, currents are induced as in the former case, the approach of the wire being marked by an inverse current, and its withdrawal by a direct one. As long, however, as the primary wire remains in any one position, all evidence of electricity in the secondary wire disappears; but if in this position the strength of the primary current should be increased or diminished, momentary currents in the secondary wire would again mark the changes in the primary, the increase causing an inverse, and the decrease a direct current. Hence we conclude, that *a current which begins, a current which approaches, or a current which increases in strength, induces an inverse momentary current in a neighboring conducting circuit*, and that *a current which stops, a current which retires, or a current which decreases in strength, induces a direct momentary current in a neighboring circuit.* For inverse, the word *negative*, and for direct, the word *positive*, are frequently employed in reference to induced currents.

In experiments like the above, it is much more convenient to wind the primary and secondary wires side by side round a bobbin, so as to form a coil. The wires are insulated from each other by a covering of wool or silk. Not only does such a disposition admit of very long wires being used, but it also disposes the wires employed to greater advantage, for each single turn of the primary wire acts not only on the corresponding turn of the secondary wire, but on all the turns near it. The inductive effect of such a coil is much greater than that which would be obtained by the same extent of wires running side by side in a straight or crooked line. It is not even necessary that the two wires be wound round together, each may be wound on a separate bobbin, and the one placed inside the other. The primary coil is made of wire one-twelfth of an in. in diameter, covered with wool; and the secondary coil of silk-covered wire, about one-eightieth of an in., and much longer than the primary wire. With two such coils, the illustration of the

preceding principles of induction can be conveniently given. If the primary coil be placed in the circuit of a galvanic cell, by two loose and flexible wires, so as to allow of its easy motion, and if the terminal binding-screws of the secondary coil be placed in connection with a galvanometer, when the primary coil is inserted into the secondary, a momentary inverse current is indicated, and when it is removed, a momentary direct one; or if, when the primary coil remains in the secondary, the strength of the primary current be altered, the needle announces the induction of currents according to the principles stated above. In order, however, to obtain the greatest effect from the secondary coil it is necessary, whilst the primary remains within it, to have some means of continuously completing and breaking the primary current. A contrivance for this purpose is called a *rheotom*, or *current-break*. A simple rheotom may be made of a common file, by holding one wire from the battery against the end of the file, and running the other along the teeth, the current being stopped each time the wire leaves a tooth. In this way, a rapid series of interruptions is effected, each of which is attended by an inverse and a direct current in the secondary wire. A break of the same description, but more constant, may be also made by causing a metal spring to press against the teeth of a metal wheel, both spring and wheel being connected with the battery. As the wheel is turned by a handle, the spring breaks the contact each time it slips from one tooth to another. The most convenient form of break, however, is one which is made self-acting by the action of an electro-magnet, which receives the name of a *magnetic hammer*.

Quantity and Tension of Induced Currents.—Let us place the primary coil within the secondary; let the primary, along with a self-acting rheotom, be put in the circuit of a galvanic cell, and let the secondary coil be connected with a galvanometer. The interruption in the primary current being effected by the rheotom with great rapidity, the induced inverse and direct currents are sent with corresponding rapidity through the coil of the galvanometer. If this last be of a short and thick wire, so as not to tax the tension of the current transmitted, the induced currents will not deflect the needle; or if they should happen, through the unsteady action of the break, to do so, it only oscillates round its position of rest. This proves that *the quantity of electricity transmitted by the induced inverse and direct currents is the same*, for they each exert the same influence on the needles. But if the coil of the galvanometer consist of a long fine wire, the needle is kept deviated in a direction which argues the action of the direct current. This leads us to conclude that *both currents, though equal in quantity, are unequal in tension, the direct current having the highest tension*, for it has more power to force its way through the fine wire of the galvanometer than the inverse. Other proofs of the same principles may be easily furnished.

The difference of the tension of the two induced currents is accounted for in this way: when a change takes place in the primary current, the quantity of the electricity induced by it in the secondary wire is the same whether this change takes place quickly or slowly; the tension, however, is very different. When the change takes place slowly, the total quantity of electricity in circulation continues to pass as slowly, and there is little in motion at one time; but when the same occurs quickly, it is sent with momentum, so to speak, and the quantity in circulation at one time is as much greater, in comparison with the former case, as the time is shorter. It is this quick dispatch of electricity which constitutes the tension of the current. Now, as it takes some time before the primary current is fully established, the inverse induced current is slow and of low tension; but when the contact is broken, the primary current ceases much more suddenly than it began, and the direct induced current is quick and of high tension. This view of the matter is borne out by experiment, for it is found, that *whatever favors the suddenness of the changes of the primary current, heightens the tension of the currents induced by these changes.* The break, from this circumstance, forms an important element in the construction of all induction apparatus.

The inductive power of the primary coil is immensely increased by placing a bundle of soft iron rods or wires in the center of it. The magnetism which begins and ceases in these at each passage of the current acts in conjunction with the inducing force of the coil. The center of the bobbin is hollow, to receive a bundle of this kind. The greater part of the inductive action is due to the iron core, and the induced currents got with and without it are not to be compared in point of energy. A solid bar of soft iron may also be used, but with much less advantage, for the induced currents which linger in it after the stoppage of the main current, acting themselves inductively, impair the suddenness with which the current disappears from the primary wire and magnetism from the core. The thin layer of oxide which forms on the rods insulates them sufficiently from one another, and prevents the formation of such currents. It is partly for the same reason that metal tubes cannot be used for bobbins for either primary or secondary coils. If such were used, *closed circuits* would be formed in them, the reaction of which would prolong the changes of the primary inducers, and consequently impair the tension of the secondary current. Metal bobbins would not be open to this objection if they had a longitudinal slit, which would make the tranverse section a broken ring and circuit.

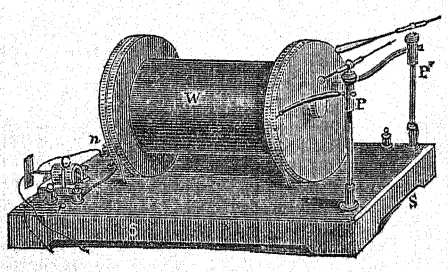
The excitation of magnetism in the core is the principal aim of the primary coil, and as a strong current is essential to that object, it is made of thick wire and of moderate length. In the secondary coil, the tension of the induced current alone is aimed at,

and with this view it is made of as thin wire as can be made, so as to admit of as many turns as possible being brought within the influence of the core and primary coil. The electric conformation of the secondary coil is sometimes looked upon in the same light as that of a galvanic battery. The total electro-motive force of the coil is the sum of that of all the turns in it, in the same way that the electro-motive force of the battery is proportionate to the number of cells.

Extra Current.—Not only does a galvanic current induce electricity in a neighboring circuit, but it also acts inductively on itself. When contact is broken in a battery circuit, the galvanic spark is seen. See GALVANISM. When the wire is short, the spark is feeble, but it increases in brilliancy with the length of the circuit, and this becomes particularly observable when the wire is wound round in a coil. This certainly does not arise from the current being strong with the long wire, and weak with the short one, for quite the reverse is the case, as might be shown with the aid of a galvanometer. The real cause of the superior brilliancy of the galvanic spark with the long circuit is to be found in the induction of the primary current on the various parts of itself, exciting, as they are called, *extra currents* in the primary wire. It has been fully attested by experiment, that at the instant *a galvanic current begins and ends, extra currents are induced by the action of the several parts of its circuit upon each other, that at the beginning of the current being inverse, and that at the end direct.* As the extra current inverse acts opposite to the main current, it does not appear as a separate current, but only retards the instantaneous passage of the main current. The extra current direct succeeds the main current, and has consequently a separate existence. It is what is generally referred to when the extra current is spoken of. This extra current is of much higher tension than the original current. The effect of the extra current on the direct induced current of the secondary coil is to lessen very decidedly its tension. If a way be made for the extra current, the tension of the induced current falls prodigiously. In a large coil-machine, which gives freely sparks of 1 or 2 in. in length, when the two portions of the break are joined by a thin wire, so as to allow the extra current to pass, sparks will not travel between the two poles, however near they are brought. When no such communication exists, a portion of the extra current leaps over between the separating parts of the break, and in so far diminishes the intensity of the secondary current. The condenser of the coil-machine, to be afterwards described, has for its object the absorption or suppression of the extra current, but the manner in which it effects this is not yet properly explained. The prejudicial effect of the extra current on the induced current is easily understood, when we bear in mind that it prolongs the cessation of the magnetism of the core and of the current in the primary coil, and thus impairing the suddenness of this change, reduces the tension of the induced current.

Induction Coil.—The essential parts of this apparatus have been already described in detail. A primary coil with its core of iron wire, and a secondary coil exterior to and insulated from a primary coil, form the main portion of the instrument. The primary coil is connected with the poles of a galvanic battery, and in the circuit a rheotom is introduced, to effect the interruptions of the current essential to its inductive action. The only parts not yet referred to are the condenser and the commutator. The condenser consists of several sheets of tinfoil and oiled silk, laid alternately the one above the other. The first, third, fifth, etc., sheets of tinfoil are connected by strips of the same material; so are the second, fourth, and sixth, etc.; the whole forming a condensing apparatus like a Leyden jar, the odd sheets forming the one coating, and the even sheets the other. Each set of sheets is connected with one of the wires of the primary coil. The condenser is generally placed in the sole of the instrument, and does not meet the eye. The commutator consists of an ivory cylinder covered with conducting plates on two sides, and is so constructed that it can break contact, or transmit the current through the coil in either direction.

An induction coil, as constructed by Ladd of London, is represented in the figure. The forms under which the instrument appears are very various, and the one in the figure only serves to show the general requirements in its construction. The two binding-screws, *p* and *n*, are for the battery wires; C is the commutator. The two coils, W, lie horizontally on the sole of the instrument, S. The secondary coil alone is seen, the primary being within it and out of view. The breaking hammer, being behind the coil, is likewise not shown. The condenser is contained by the box which constitutes the sole, and a conducting connection is established between its coatings and the wires of the primary coil. The terminations of the secondary coil are fixed to the heads of the glass pillars, P, P', which are furnished with pointed rods capable of universal motion. The excellence of the instrument depends on the proper insulation of the secondary coil. The bobbin must be made of glass, gutta-



percha, or (best of all) vulcanite, so as to prevent the induced electricity from reaching the ground by the primary coil Care must also be taken to insulate the different parts of the secondary coil from each other. If this were not done, the spark which completes the secondary current, instead of taking place at the rods, the place at which it is wanted, would pass within the coil itself. It is necessary, in consequence, to have each layer of the coil insulated from the other, by interposing gutta-percha paper, and cementing it with a hot iron to the sides of the bobbin. The induced current must thus pass through all the turns of the wire, and is prevented from shortening its course by leaping over one or more layers of the coil.

Experiments with the Induction Coil.—Say that we experiment with a coil like the one shown in the figure about 1 ft. long and nearly 6 in. in diameter, which yields readily sparks of from 4 to 5 in. with a battery of 6 Bunsen cells. After connecting the battery-wires, and setting the commutator so as to complete the contact, let us place the movable rods within an inch of each other. An uninterrupted rush of sparks is transmitted between the points of the rods. The sparks are not the clear single sparks of the electric machine, but seem to be made up of several sparks occurring at the same instant, which are white and crooked. These are enveloped in a luminous haze, which, on closer examination, wears the appearance of a congregation of the spiral sparks, the convolutions of which are in constant rotation. This hazy spark can be blown away by the breath, and separated from the white spark, which cannot be so removed. As the rods are withdrawn from each other, it disappears, and when they stand above 3 in. apart, the spark resembles in every respect the forked single spark of a powerful electric machine. When the points are withdrawn beyond striking distance, electric brushes still play between them, which become visible in a darkened room. If the hand be brought near the rod connected with the exterior end of the coil, sharp stinging sparks, 2 or 3 in. in length, are got. The rod connected with the inner end does not yield them so readily, and this is the same whether it be the positive or negative pole. When a gold-leaf electroscope is brought near, the leaves part energetically from each other; and when a spark is received by it from one of the rods, it remains permanently charged. When, however, the knob of the electroscope is brought into actual contact with either of the rods, this action ceases, because the induced currents, inverse and direct, neutralize each other. When the knob touches, both currents affect the leaves equally; but when it is at some distance, the direct current alone has tension enough to act. Each pole of the induction coil is the seat of two opposite electricities, alternating with each other, alike in quantity, but differing in tension, and this accounts for the resemblances and differences between the coil and machine electricities. When the poles are put in connection with the coatings of a Leyden jar, the sparks passing between the points are much more brilliant, and the sharp snap of the simple spark grows into a loud report. The Leyden jar effects a condensation of the electricity of each direct current, and each spark discharge takes place in shorter time, and consequently with greater intensity. The condensed spark punctures paper and the like with great facility, but it is of very low heating power. The uncondensed spark, more particularly the hazy spark, got when the poles are near each other, kindles paper, gunpowder, coal-gas, and other combustibles with readiness and certainty. It is from this property of its spark that the induction coil is of so great use in mining operations. The two ends of the wires coming from the coil are fixed near each other without touching, and are imbedded in a charge of gunpowder at a safe distance from the operator. The wires are insulated by gutta-percha, and when the induced current is sent through them, sparks pass through the gunpowder between the ends of the wires, and set fire to it. When several charges have to be ignited simultaneously, the spark of the coil-machine is considered much more reliable than the action of a powerful galvanic battery in heating thin wires connecting the ends of the battery-wires. See GALVANISM. The power of the direct induced current of even large induction coils to deflect the magnetic needle, and to effect chemical decomposition, is very insignificant. This shows that it is very much inferior to the inducing current in quantity, however much it may be superior in tension. The physiological effect, on the other hand, is tremendous, and the experimenter must take care not to allow any part of his body to form the medium of communication between the poles, as the shock so got might be dangerous, if not fatal.

When the induced current is made to pass through nearly vacuous spaces, a very splendid effect is produced The *electric egg* is employed to display this. It consists of a glass vessel in the shape of an egg, with an open neck above, and another below. Brass fittings are attached to these. The lower opening is fitted with a stop cock, and can be screwed to the plate of an air-pump. A brass rod and ball rise a short way into the egg. The fittings above are intended to allow of a rod ending in a ball passing up and down air-tight, so that the two balls can be conveniently set at different distances. When the egg is exhausted, and the wires from the coil are attached, the one above, and the other below, a luminous glow extends between the balls, which is wide in the middle, and contracts at either extremity. When the exhaustion has reached one-twelfth of an inch, as shown by the gauge of the air-pump, black bands are seen to lie horizontally in the light, so as to wear the appearance of stratification. These occur more readily when a drop or two of turpentine, alcohol, or ether have been introduced into the egg. The cause of the stratification is as yet a matter of speculation. The ball which forms the

negative pole is enveloped in a covering of blue light. The glow, which is of a beautiful mauve tint, appears to proceed from the positive ball, and reaches nearly to the negative ball, from which it is separated by a well-marked non-luminous space. By means of the commutator, these appearances at the balls can be instantly transposed. Serving the same purpose as the electric egg, there is a great variety of vacuous tubes hermetically sealed and ready for use at any time. These have been first filled with particular gases, and then exhausted, and they exhibit lights of various tints, according to the gas contained by them.

INDULGENCE, in Roman Catholic theology, means a remission, by church authority, to a repentant sinner, of the *temporal* punishment which, in the Catholic theory, remains due after the sin and its eternal punishment have been remitted. A doctrine which has been the subject of so much angry controversy, and which may be regarded as the chief among the proximate causes of the reformation, deserves very careful consideration. We must confine ourselves, however, to a brief authentic explanation of the doctrine such as it is held by Roman Catholics, together with a history of the practice in the various ages of the church.

By the discipline of the first centuries, a severe course of penitential observance was exacted of all who fell into any grievous crime, especially apostasy, murder, and adultery, such sinners being excluded from church communion for various periods, in some cases even till the hour of death. These penitential observances, which Protestants regard as purely disciplinary, were designed, according to the Catholic view, as an expiation, on the part of the penitent, for the *temporal* punishment which, after sin and the *eternal* punishment due to it have been remitted by God, still remains to be undergone; and some of the most acrimonious of the early controversies, the Montanist and the Novatian, arose as to the power of the church to relax these penitential observances, and to admit grievous sinners to communion. These ancient relaxations (of which they regard that referred to in 1 Cor. v. 5 and in 2 Cor. ii. 10 as a type) are considered by Catholics as examples of the modern indulgence; and the practice which grew up in the 3d and 4th centuries, and which even then was carried to great extremes, of granting such relaxations on the recommendation of martyrs or confessors, is held by Catholic theologians to be an illustration of that principle of vicarious atonement, according to which, in the theory of indulgences, the church is supposed to supply, from the inexhaustible treasure of the merits of Christ, and of the "supererogatory" works of the saints, what may be wanting to the completeness of the atonement of the less perfect but yet truly penitent sinner to whom she grants the indulgence. That this practice of relaxation, whatever may have been its real import, was to be used according to the judgment of the bishop as to the disposition of the penitent, is expressly laid down by the council of Ancyra in 308, and by that of Nice in 325. In all cases, however, the person granting the relaxation was to impose certain good works as a partial substitute for the penalty which had been relaxed; and among these works, which had at first been purely personal, came by degrees to be included money payments for certain religious or charitable objects, as the building of a church, or the foundation of a monastery or hospital. The name indulgence appears to have originated late, the first recorded instance of its use being by Alexander II. in the 11th c.; but the institution itself is found in full development during the wars of the crusades, the serving, or the contributing to service in which, "provided it were for devotion alone, and not from motives of greed or of glory," was accepted in the council of Clermont "as an equivalent substitute for all penance." Such an indulgence was called "plenary;" where a portion only of the penitential works was relaxed, it was called "partial;" and in order to put a bar to their excessive multiplication and to other abuses, Innocent III. declared the power of granting "plenary indulgences" to be reserved to the pope alone, bishops being only authorized to grant the "partial" or limited indulgences described above. The fourth Lateran council condemns the "indiscreet and superfluous" granting of indulgences; and among the abuses which grew up in the church during the western schism, one of the most remarkable was the lavish dispensation of indulgences, in the granting of which the contending popes rivaled each other in prodigality. The last extreme, however, was not reached until the beginning of the 16th c., when, with a view to raising the funds necessary for the erection of the great church of St. Peter's at Rome, the pope, Leo X., published a plenary indulgence, the principal condition for the gaining of which was a contribution to this work. Catholic historians contend that in itself such a condition was perfectly justifiable, and that if duly explained to the people, it might be lawfully and even meritoriously complied with; but they admit that many of the preachers of the indulgence, in extolling its natural effects, went to indefensible extremes, and that, even making the fullest allowance for exaggeration, it cannot be denied that grievous abuses both of doctrine and of practice were committed in Germany and in Switzerland. Hence the decree of the council of Trent, while it affirms that the use of indulgences, as being "most salutary for the Christian people, and approved by the authority of councils, is to be retained in the church," yet orders that, "in granting them, moderation be observed, lest, by excessive facility, discipline may be enervated." Upon the special instructions of this council all the modern legislation on the subject of indulgences has

been founded; but as the decree of the council does not explicitly declare what is the precise effect of an indulgence, it is further explained by Pope Pius VI., in his celebrated bull, *Auctorem Fidei*, that an indulgence, received with due dispositions, remits not alone the canonical penance attached to certain crimes in this life, but also the temporal punishment which would await the penitent after death to be endured by him in purgatory.

From the above explanation, it will be gathered that Catholics do not understand by an indulgence a remission of sin, much less a permission to commit sin, or a promise of forgiveness of future sin. They contend, moreover, that since the benefit of an indulgence can only be enjoyed by a sinner who has repented of sin and resolved to embrace a new life, the imputation of introducing laxity of principle and easy self-indulgence is entirely unwarranted. And although, for the most part, the good works which are required as the condition of obtaining indulgences may appear easy and even trivial, yet the one indispensable preliminary—sorrow for sin and sincere purpose of amendment—in itself involves the very highest effort of Christian virtue.

On the subject of indulgences, Protestants are accustomed to quote the language used by popes in granting them, in opposition to the views put forth by Roman Catholics in defending them. And nothing is more common than for popes in their bulls of jubilee to grant *the most plenary and complete indulgence, pardon, and remission of all sins*, on certain conditions specified. And although this grant is made only to "the faithful who are truly penitent and have confessed," yet being limited to a certain period, as the year of jubilee, and to certain conditions, as saying certain prayers, visiting certain churches, wearing or kissing a scapular, or the like, it is argued that these cannot but acquire, in the estimation of the people, an importance which is very unfavorable to penitence, virtue, faith, and piety. It is likewise urged that the whole doctrine of indulgences is founded not only on an unwarranted assumption of power given to the church, but also on a doctrine of human works and merits inconsistent with what we are taught in Scripture as to the office of Christ as a Savior.

IN DUS (Sans. *Sindhu*, probably from a root signifying "to flow"), the great river that bounds Hindustan on the west. It rises in Thibet, near the sources of the kindred Sutlej, in lat. 31° 20′ n., and long. 81° 30′ east. The precise spot is said to be 18,000 ft. above the level of the sea, and to be on the n. side of the Kailas, a Himalayan peak which overtops it by at least 4,000 feet. Its general course, till it forces its way between the Himalaya proper and the Hindu Kush, is towards the n.w., being pretty nearly at right angles to its general direction through the plains. On reaching Sussi (near the borders of Budakshan), its most northern point, it turns southward, loses itself in the hills, and reappears at Takot in Kohistan, n. of the Punjab. After a run of 870 m., having still 940 m. before it, it becomes navigable at a point which, on other grounds also, is worthy of notice. Here it receives the Cabul, its principal affluent on the right; and here is Atak (Attock), anciently Taxila, the scene of Alexander the great's passage. About half-way from Atak to its mouth, it receives, on the left, the accumulated waters of the Punjab through the single channel of the Punjnud. Each of the "five water-courses," as well as the Cabul, is practicable for inland craft to the mountains. Below its confluence with the Punjnud the Indus, instead of increasing in volume, becomes gradually less. Its basin is here narrow, so that the affluents are insignificant, while its arid sandy nature causes the river to suffer from absorption and evaporation. This operates still more powerfully from the circumstance that the river here divides into numerous channels, many of which never return at all to the main stream, while others return much shrunken in volume. This wasting of the waters is, however, not very apparent to the eye, owing to the gradual slackening of the current and the ascent of the tides. At Migani, 8 m. n. of Hyderabad, commences the Delta proper, which measures 75 m. upwards, by 130 along the coast of the Arabian sea. The area of the drainage—its extreme dimensions being respectively 900 m. and 750—has perhaps been overestimated at 488,000 sq.m., fully four times the extent of Great Britain and Ireland.

The value of the Indus as a route of traffic is less than that of most other streams of equal magnitude. In the winter, one only of its numerous outlets is at all available for communication with the sea; and even after the melting of the spring snows, there is no passage anywhere for an ordinary sea-going vessel of more than fifty tons. Still, in another respect the river is favorable for navigation, as the fall from Atak to the sea is only 1000 feet in 940 miles.

The Indus abounds with fish of excellent quality, and is infested by crocodiles. The alluvium brought down by the stream has been calculated to be sufficient for an annual formation 42 m. long, 27 m. broad, and 40 ft. deep. Near Rori, a short distance below the first point of divergence, both the main stream and one of its offsets pass through a ridge of limestone, which must at one time have turned the descending floods laterally into what is now a desert, but bearing the plainest traces of former cultivation.

INDUSIAL LIMESTONE, a singular variety of fresh-water limestone, found in Auvergne. It is formed of the cases of indusia or caddis-worms, great heaps of which have been incrusted with carbonate of lime, and formed into a hard travertine. Several beds occur, some as much as 6 ft. thick, each cubic inch of which contains as many

as ten or twelve cases. See CADDICE. The Auvergne cases are formed of the shells of a minute paludina, so small that 100 shells may be counted in a single indusium.

INDUSTRIAL ACCESSION, a phrase borrowed by the Scotch from the Roman law to denote the increased value given to a thing by labor and skill being exercised upon it. This phrase includes the case of a person building by mistake on another's land, in which case, in England, though the building was done *bonâ fide*, it belongs absolutely to the owner of the land, who is not bound even to pay for the materials, which he can keep, or their value; but in Scotland, the owner of the land, though entitled to the materials, would be liable to pay for their value.

INDUSTRIAL EXHIBITION. See EXHIBITION, INDUSTRIAL, *ante*.

INDUSTRIAL FRUITS, in Scotch law, the produce of land which the life-renter is entitled to; called in English law, emblements (q.v.).

INDUSTRIAL INSTITUTIONS. See AGRICULTURAL INSTITUTIONS; JUVENILE OFFENDERS.

INDUSTRIAL SCHOOLS. This term is used very variously, sometimes being synonymous with ragged schools, in which mechanical arts are taught; sometimes designating ordinary elementary schools, in which agricultural or some other industrial art is taught to the boys during one portion of the school-day, or in which sewing, cooking, washing, and ironing are taught to the girls. In England, Scotland, and Ireland, attempts have been made to attach practical instruction in agriculture to elementary schools for boys, but with very small success, except in the last-named country; there the Glasnevin agricultural training school has accomplished much good. See AGRICULTURAL EDUCATION. Nor can it be said that the attempt to attach other industrial arts to national and parochial schools has been attended with better results. The privy council on education gave special grants for many years to schools which combined industrial with literary instruction, but these grants are not continued in the revised code. In elementary schools for girls, industrial work, to the extent of sewing, shaping, knitting, and netting, has been almost universally introduced, and forms one of the most important and interesting features of female primary education in Great Britain; but the attempt to connect with these subjects instruction in cooking, washing, and ironing, has been tried as yet only to a limited extent, and has been only partially successful. In ragged schools, on the other hand, no department of the school-work seems to thrive better, partly because it enters so largely into the scheme of instruction, partly because the children are removed from the control of parents, and left solely to the management of the school committee; for the great obstacle in the way of connecting industrial arts with ordinary schools is the unwillingness of parents to see their children engaged in manual occupations during the time which ought, in their opinion, to be devoted solely to intellectual training and the acquisition of literary knowledge. The ragged schools to which we have just referred are recognized by the legislature as "industrial schools," to the maintenance of which the treasury may contribute on the representation of the home secretary, and may be defined as schools in which the pupils are lodged, fed, and clothed, as well as taught the elements of an ordinary education, and the practice of some trade. By a statute passed in 1866 children under 14 found begging, etc.; children under 12 charged with offenses; refractory children under 14 in charge of parent; and refractory children under 14 in workhouses or pauper schools, may be sent by a magistrate to a certified industrial school. The education acts of 1870 and 1872, for England and Scotland respectively, provide that the school-board of any parish or borough may establish and maintain industrial schools, but subject to the provisions of the industrial schools act of 1866. In 1875 the number of industrial schools in England and Scotland was 114, containing 11,776 children; in 1877 there were 124 schools, with 14,359 children.

INDUSTRIAL SOCIETIES are societies which carry on some trade, the profits of which are applied to an object of mutual benefit, resembling the object of friendly societies (q.v.). The "Industrial and Provident societies act, 1876," regulates these societies on improved principles, the first statute having been passed in 1852. Any number of persons not less than seven may establish such a society for the purpose of carrying on any labor, trade, or handicraft, whether wholesale or retail, or the buying and selling of land, or the business of banking under certain restrictions, and taking deposits only under 5s. in one payment, and under £20 from one person. The rules of the society must define the object, name, and place of office of the society, and it must in all cases be registered as one of limited liability. The rules and statute define terms of admission of members, mode of holding meetings, voting, transferability of shares, audit of accounts, investment of capital, mode of withdrawing from the society, claims of executors, application of profits, appointment and remuneration of managers and officers, and make provision for the custody, use and device, of the seal of the society. Rules must be forwarded to the registrar of friendly societies of England and Scotland, for his certificate that they are in conformity with law, before they can be acted upon. After registration a copy of the rules must be delivered to every person who demands them, on payment of one shilling. No member's interest is to exceed £200, but one society may invest its funds with another or others to any amount. The name of the society is to be

painted conspicuously on the outside of the office, and put on all bills of exchange, bills of parcels, invoices, receipts, and letters of credit, and a penalty is incurred for neglecting these requirements. These societies are placed on the same footing as friendly societies in respect of the exemption from assessment under income-tax—of settlement of disputes by registrar, justices, or county court—of compensation to members unjustly excluded—of the power of justices or the county courts in case of fraud, and of the jurisdiction of the registrar. Any member may nominate any person into whose name his interest in the society at his decease shall be transferred, but the society *may*, instead of making such transfer, pay to any nominee the full value of the shares, and *must* pay him the value of any shares, which, if transferred into his name, would increase his interest in the society to more than £200. The society may be wound up like a joint-stock company by the county court of the district, and in the event of its being wound up, past and present members are liable to contribute to the assets to an amount sufficient to pay the debts; but no past member is bound to contribute who has ceased for a year to be a member, or where the debt was contracted after he left the society, or unless the existing members are unable to satisfy the contributions necessary to pay the debts; and no member is liable to pay more than the amount, if any, unpaid on the shares in respect of which he is liable as a past or present member. Every person or member having an interest in the funds is entitled to inspect the books. A general statement of the funds of the society, showing the assets and liabilities, must be sent to the registrar once every year, and every member and depositor is entitled to demand and receive without payment a copy of such statement from the treasurer or secretary.

INEQUALITY. In algebra the relationship existing between two quantities can be expressed either by the sign of equality, as $a = b$, or by the sign of inequality, as $a > b$ and $c < d$, read respectively a is greater than b and c is less than d: the greater quantity—that which more nearly approaches to $+\infty$—is always opposite the opening of the angle. The first members are a and c; the second, b and d. When in two inequalities the greater quantity is on the same side of the sign, they subsist in the *same sense*, and when on different sides they subsist in a *contrary sense*.

INERTIA (Lat. "inactivity"), a term expressive of that indifference to a state of rest or motion which is a universal property of matter, and may be expressed by saying *that a body in motion will continue in motion, and a body at rest will remain at rest, unless acted upon by some external force.* The latter part of this principle was known to the ancients, and by them attributed to a certain repugnance to motion, which was a characteristic of all matter; but it was shown by Galileo that the former part was equally true and general. This property of matter has been called by Kepler *vis inertiæ*.

INES DE CASTRO. See CASTRO, INES DE, *ante*.

INESCUTCHEON, in heraldry, a single shield borne as a charge. When there are two or more, they are simply called escutcheons, for an inescutcheon, it is said, must always occupy the fess point of the shield. An inescutcheon is to be distinguished from an escutcheon of pretense, which is not a charge, but a separate coat.

INFALLIBILITY, in controversial theology, means the immunity from error, in all that regards faith and morals, which is claimed by the Roman Catholic church, and, at least as regards the past, by the Greek church, as represented in the decrees of the councils which that church looks upon as ecumenical. The latter claim, however, which does not go beyond that of *inerrancy*, or actual exemption from error up to the present time, differs widely from that of infallibility, as put forward by the Roman church, which involves not alone an actual historical immunity from error, but also such a positive and abiding assistance of the Spirit of God as will at all times both protect against the possibility of error, and guide and direct in the faithful teaching of all necessary truth. The infallibility claimed by the Roman church is thus of two kinds, *passive* and *active*—the first (Matt. xvi. 18), in virtue of which the church never can *receive* or *embrace* any erroneous doctrine, no matter by whom proposed; the second, in virtue of which she is charged with the function (Matt. xxviii. 19; Mark xvi. 15; Ephes. iv. 11–16) of permanently *teaching* to the world the essential truths of God, of actively resisting every access of error, and of authoritatively deciding every controversy by which the oneness of belief among the faithful may be endangered. Catholics regard this gift as a natural and necessary accompaniment of the authority in matters of faith with which they believe the church to be invested, and which, if not guided in its exercise by such infallible assistance, would be but a false light, and an attractive but dangerous instrument of delusion.

Such is the notion of infallibility as claimed by the Roman church. Two very important and practical questions, however, arise regarding it, both of which have been the occasion of much controversy even among Catholics themselves; viz., as to the *subject*, that is, the seat or the organ of this infallibility, and as to the *object*, that is, the matters to which it extends.

As to the first, all Catholics have been agreed that the body of bishops, morally speaking, throughout the church, acting in common with the pope, constitute the most perfect organ of the infallibility of the church; and hence, that when they unite in any way, whether as assembled in a general council or separated in place, their judgment is

infallible. Thus, if a doctrinal decree be addressed officially by the pope to the whole church, and be either expressly confirmed or tacitly accepted by the bishops, this decree was held to be infallible. In like manner, if a doctrinal decree, emanating even from a local council, as that of a national or even a provincial church, should be universally accepted by the pope and the bishops, that decree also was held to be infallible. In a word, wherever there is found the *united* judgment of the pope and the bishops, all agreed in accepting it as the infallible judgment of the church. But should the pope alone judge without the bishops, then arose the well-known dispute of the Gallican and ultramontane divines; the latter affirming, the former denying, the papal judgment to be infallible; but all agreeing that it was not binding *as an article of Catholic faith*, so long as it had not received the assent of the body of the bishops. By the decree of the Vatican council, 1870, this controversy has been decided; and it is now agreed that the doctrinal decrees of the pope teaching *ex cathedrâ* are to be accepted as possessing the same infallibility which attaches to the teaching of the church. See COUNCIL.

On the matters or subjects to which the gift of infallibility extends Catholics are agreed in one principle, that it embraces all those subjects, and those only, which are necessary for the maintenance of divine truth in the church. Hence, presupposing divine revelation, either written or oral, it embraces all questions of faith and morality, all subjects of general discipline, so far at least as to preclude the introduction, by authority of the church, of any discipline which should be injurious to faith or to morality. On the other hand, it does not embrace questions of science, or matters of fact, or abstract opinions unconnected with religion. On this point all Catholics have been agreed. But a very celebrated dispute arose in the 17th c., on occasion of the *Augustinus* of Jansenius, as to the infallibility of the church in judging of books, out of which originated the well-known Jansenist distinction of *law* and of *fact*. See JANSENISM. On this subject, it will be enough to say, that all Catholics are now agreed in recognizing as a necessary condition to the effective infallibility, that it should extend to the judgments upon books so far as to decide whether the doctrine contained therein may or may not be opposed to sound faith or morality.

The arguments in favor of the infallibility of the church, which Roman Catholics derive from texts of Scripture, are set aside by Protestants on the ground that these texts only teach the permanence of the church and the continuance of God's grace towards it (as Matt. xvi. 18; Matt. xxviii. 19, 20; etc.), and have no relation whatever to the special subject of infallibility.—It is common also for Protestants to urge that on the supposition of infallibility and of the need of an infallible interpreter of Scripture, as commonly declared by Roman Catholics, there can be no value in any argument from Scripture; and that the Roman Catholic theologian, in attempting to prove the infallibility of the church by Scripture, and the authority of Scripture by the infallibility of the church, is involved in the sophism of reasoning in a circle.—It is sometimes added that if God's word needs an interpreter to make it a safe rule of faith, man's word may well be supposed equally difficult to comprehend.—And the notion of infallibility, with the whole system of which it forms an essential part, is protested against as contrary to the rational nature of man, and to that personal relation and responsibility to God which are at the foundation of all true religion. Something is also made in argument of the difficulty which the advocates of the infallibility of the church have found in agreeing as to where it is lodged.

INFAMED, or DEFAMED, in heraldry, an epithet applied to a lion or other animal which has lost its tail, the loss being supposed to disgrace or defame it. *Defamed looking backwards* occurs in ancient blazon for counter-rampant regardant, the lion being supposed to be flying from an enemy.

INFAMOUS. Infamy was, in point of law, formerly a ground for rejecting a witness in a court of justice; but now, in the United Kingdom, the witness is allowed to give evidence subject to comment, and to state what he can say for what it is worth.

INFAMOUS BEHAVIOR—DISCHARGE WITH INFAMY, terms in use in the military and naval codes to designate conduct (and its penalty) which is not only opposed to discipline, but is also disgraceful in a social sense. As infamous behavior, have been always classed in all countries desertion of colors on the field of battle, failure to attempt to succor comrades in danger, cold-blooded cruelty, and other crimes which are greatly subversive of morality. If a man is found guilty of any of these crimes by a court-martial, and not sentenced to death, the sentence is ordinarily discharge—or dismissal—with ignominy or infamy. So severe an enactment adds to the force of the penalty, and stigmatizes the offender for life as a disgrace to his country and his cloth.
